Connected treewidth Layout Series-parallel graphs

Treewidth

Definition

A tree decomposition T of a graph G = (V,E) is a tree where nodes are subset of V_G. Each vertex and each edge appear in T and $\forall x \in V$, the set of nodes containing x has to induce a connected sub-tree of T.

Treewidth

Let G be a graph. The width of a tree decomposition T of G is width(T) = max{ $|X| - 1 | X \in T$ }. The treewidth of the graph G is tw(G) = min_T{width(T) with T a tree decomposition of G}.

Connected treewidth

Connected treewidth

A tree decomposition T is connected if there exists *r* such that for every path *p* from *r*, the subgraph of G induces by the vertices in *p* is a connected subgrah of G. The connected treewidth of a graph G is $ctw(G) = min_{T} \{width(T) with T a connected tree decomposition of G\}$.

Tree vertex separation number

We denote $\operatorname{tvs}(\mathsf{G}) = \min_{\sigma} \max_{i \in [1,n]} |S_{\sigma}(i)|$.

Connected treewidth Layout Series-parallel graphs

Connected layout

Connected layout

Let G be a connected graph. A layout σ is a connected layout if one of the two following equivalent proprieties are satisfied:

- $\forall i \in V_G, G[\sigma_{\leq i}]$ induces a connected subgraph of G.
- $\forall i \in V_{G}, \exists j \text{ such that } \sigma_{j} \text{ is a neighbour of } \sigma_{i} \text{ with } j < i$.

Connected tree vertex separation number

We denote $\operatorname{ctvs}(G) = \min_{\sigma} \max_{i \in [1,n]} |S_{\sigma}(i)|$ with σ a connected layout.

(日)

Results

Theorem

- [Dendris N., Kirousis L., Thilikos D. TCS'97]: tw(G) = tvs(G).
- [Adler I., Paul C., Thilikos D. FST-TCS'19]: ctw(G) = ctvs(G).
- Price of connectivity: $\forall k \in N$, there exists G such that

 $\mathsf{ctw}(\mathsf{G}) - \mathsf{tw}(\mathsf{G}) \ge k.$

Our result

[Mescoff G., Paul C., Thilikos D.]: We can compute the connected treewidth of series-parallel graphs in $\mathcal{O}(n^2 \cdot \log n)$ time where *n* is the number of vertices of G.

Extended graph

Extended graph

Let G=(V,E) a graph and F a set of edges disjoint from $E_G.$ We denote G^{+F} the extended graph G with with fictive edges from F. We said that G is the solid graph of $G^{+F}.$

Connexity of G^{+F}

Fictive edges do not increase connexity of $\mathsf{G}^{+\mathsf{F}}.$ Connected components of $\mathsf{G}^{+\mathsf{F}}$ are exactly the connected components of the solid graph G.

Complexity

Complexity

Let G a biconnected graph.

- $\operatorname{ctw}(\mathsf{G}) = \min_{(x,y)\in\mathsf{G}}(\mathsf{G}^{+\emptyset}, \{x,y\}) \leftarrow \mathcal{O}(n).$
- We have at most 2n steps in our algorithm $\leftarrow O(n)$.
- For each step, we compute at most αn results with some constant α ← O(n).

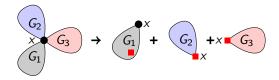

Which gives a total time complexity in $\mathcal{O}(n^3)$. With a better complexity analysis, we can show that the real time complexity is $\mathcal{O}(n^2 \cdot \log n)$.

Preliminaries definitions Composition lemmas Proof Dynamical programming Generalization for graph of treewidth at most 2

Generalization

Treewidth at most 2

A graph G has treewidth at most 2 iff its biconnected components are series-parallel graphs. So, G contain a cut vertex or G is a biconnected series-parallel graph.

Complexity

Since the complexity is $\mathcal{O}(n^2 \cdot \log n)$ for every biconnected component and since we try for every starting vertex, the total time complexity is $\mathcal{O}(n^3 \cdot \log n)$.

Conclusion

Conclusion

We see in this presentation how compute the connected treewidth for graph with treewidth at most 2. The complexity of the general problem is still open:

- **Conjecture 1:** Connected treewidth can be computed by an $\mathcal{O}(n^{f(\mathsf{tw}(\mathsf{G}))})$ -time algorithm.
- **Conjecture 2:** Connected treewidth bounded by *k* can be decided by an $\mathcal{O}(n \cdot f(k, \operatorname{tw}(G)))$ -time algorithm.
- Conjecture 3: Connected treewidth bounded by k can be decided by an O(n^{f(k)})-time algorithm.
