Facts about the brain

General:

- > All of the $\approx 10^{10}$ humans have a brain (that's controversial)
- ► Humans have $\approx 10^{11}$ neurons (don't tell Suzana Herculano)
- Humans have $\approx 10^{12}$ glia cells
- The worm C. Elegans has $\approx 3 \times 10^2$ neurons.
- Each neuron has 10³-10⁴ synapses
- A giraffe axon can have 4.5 meters
- Funding for the European Human Brain Project is €10⁹

(日) (日) (日) (日) (日) (日) (日)

Funding for the US BRAIN initiative is US\$3 × 10⁹

Modeling the brain

Almost anything goes—pick your favorite tool. In terms of math:

- Model individual neurons
 - equations based on physiology
 - ad hoc models
- Model brain regions/human behavior
 - homogenization (reaction-advection-diffusion unsteady nonlinear eqtns, Volterra eqtns)

(日) (日) (日) (日) (日) (日) (日)

- neural networks, Petri nets
- connect several individual neuron models

A crash course in neuroscience A neuron has:

- soma
- dendrites
- axon

Reality bites

Mathematical Neuron

- domain given by a tree
 - system of nonlinear time dependent equations in each branch
 - a several level multiscale problem: refined modeling of a forest

How neurons work

ionic gates:

- allow ionic flow through membrane
- voltage dependent

Neuronal signaling:

- action potential is information
- ionic concentration gradient generates electric potential

Action potential

nonlinear behavior causing ionic gates to open and close

Hodgkin–Huxley Model

They knew a model should look like:

$$c_M \frac{\partial V}{\partial t} = \epsilon \frac{\partial^2 V}{\partial x^2} - \sum_{i \in \text{ions}} g_i(V)(V - E_i)$$

where:

- c_M, ϵ, E_i : constants
- g_i: conductivity with respect to ion *i*, that depends on V (in a unknown fashion)
- Hodgkin–Huxley postulate: g_i depend on V through ODEs

(日) (日) (日) (日) (日) (日) (日)

Hodgkin–Huxley Model

$$c_{M}\frac{\partial V}{\partial t} = \epsilon \frac{\partial^{2} V}{\partial x^{2}} - \bar{g}_{K}n^{4}(V - E_{K}) - \bar{g}_{Na}m^{3}h(V - E_{Na}) - \bar{g}_{L}(V - E_{L})$$
$$\frac{dn}{dt} = \alpha_{n}(V)(1 - n) - \beta_{n}(V)n$$
$$\frac{dm}{dt} = \alpha_{m}(V)(1 - m) - \beta_{m}(V)m$$
$$\frac{dh}{dt} = \alpha_{h}(V)(1 - h) - \beta_{h}(V)h$$

Obtained by fitting the data:

$$\alpha_n(V) = 0.001(V + 55) / \{1 - \exp[-(V + 55)/10]\},$$

$$\beta_n(V) = 0.125 \exp[-(V + 65)/80], \dots$$

Constants: ϵ , c_M , \bar{g}_K , E_K , \bar{g}_{Na} , E_{Na} , \bar{g}_L , E_L

Spatial Domain

In the neuronal tree:

- HH eqtns over the edges
- transmission conditions on the bifurcations
 - continuity of voltage
 - conservation of current

At the bifurcations:

$$V|_{e_1}(\boldsymbol{p}) = V|_{e_2}(\boldsymbol{p}) = V|_{e_3}(\boldsymbol{p}),$$
$$\frac{\partial V}{\partial n}\Big|_{e_1}(\boldsymbol{p}) + \frac{\partial V}{\partial n}\Big|_{e_2}(\boldsymbol{p}) + \frac{\partial V}{\partial n}\Big|_{e_3}(\boldsymbol{p}) = 0$$
$$\underbrace{e_1 \qquad \boldsymbol{p}}_{\boldsymbol{e_3}} \underbrace{e_3}_{\boldsymbol{e_3}}$$

▲□▶▲□▶▲□▶▲□▶ □ のQ@

Numerical Scheme

Time discretization

- 1. at each time step
 - 1.1 solve the ODEs
 - 1.2 obtain a linear, time independent PDE in the tree
 - 1.3 solve the PDE using domain decomposition

Spatial discretization

- 1. "break" the domain at the bifurcations
- 2. solve the resulting one-dimensional eqtns in parallel
- 3. solve a "small" ($\sim \#$ bifurcations) system to obtain the global sltn

Time discretization of the Hodgkin–Huxley Model

Given the data at time t_j , find the conductances at t_{j+1} :

$$\frac{n_{j+1} - n_j}{\delta t} = \alpha_n(V_j)(1 - n_{j+1}) - \beta_n(V_j)n_{j+1}$$
$$\frac{m_{j+1} - m_j}{\delta t} = \alpha_m(V_j)(1 - m_{j+1}) - \beta_m(V_j)m_{j+1}$$
$$\frac{h_{j+1} - h_j}{\delta t} = \alpha_h(V_j)(1 - h_{j+1}) - \beta_h(V_j)h_{j+1}$$

Remark

- update n, m, h at the nodes for finite difference methods. and at integration points for finite elements
- do it in parallel: updates are independent

Spatial discretization of the Hodgkin–Huxley Model Find V_{i+1} by solving:

$$c_{M} \frac{V_{j+1} - V_{j}}{\delta t} = \epsilon \frac{\partial^{2} V_{j+1}}{\partial x^{2}} - \bar{g}_{K} n_{j+1}^{4} (V_{j+1} - E_{K}) - \bar{g}_{Na} m_{j+1}^{3} h(V_{j+1} - E_{Na}) - \bar{g}_{L} (V_{j+1} - E_{L})$$

Rewriting:

$$-\epsilon \delta t \frac{\partial^2 V_{j+1}}{\partial x^2} + \sigma V_{j+1} = I$$

where

$$\sigma = c_M + \bar{g}_K \delta t n_{j+1}^4 + \bar{g}_{Na} \delta t m_{j+1}^3 h + \bar{g}_L \delta t,$$

$$I = \bar{g}_K \delta t n_{j+1}^4 E_K + \bar{g}_{Na} \delta t m_{j+1}^3 h E_{Na} + \bar{g}_L \delta t E_L + c_M V_j$$

(ロ) (型) (主) (主) (三) の(で)

Domain decomposition for spatial discretizations

- In parallel
 - \tilde{V}_i solve PDE on e_i with $\tilde{V}_i(\boldsymbol{p}) = 1$ and zero rhs
 - ▶ *Ŷ_i* solve PDE on *e_i* with zero Dirichlet b.c., and nonzero rhs
 - define $\lambda = V(\mathbf{p})$
 - then $V|_{e_i} = \lambda \tilde{V}_i + \hat{V}_i$
- Sequential
 - find λ by conservation of current

MHM:

- switch roles between Dirichlet and Neumann b.c.
- no need to post-process to obtain derivatives at endpoints
- weaker boundary layers
- larger final systems (for λ)

Remarks on the one-dimensional problem

The PDE

$$-\epsilon \delta t \frac{\partial^2 V_{j+1}}{\partial x^2} + \sigma V_{j+1} = I$$

is peculiar:

- nice: simplest methods yield tridiagonal matrices
- be careful: it's singularly perturbed
- but it's 1D, so it's not that bad
- MsFEM is nodally exact
- but σ is known only at a finite number of points

Current applications

Goal: develop a software able to perform efficient neuronal simulations (A. Gomes (LNCC), C. Bajaj (U.T. Austin), D. Abrunhosa (LNCC))

Steps:

- incorporate data from refined and spatially realistic reconstruction of neurons from electron microscopy
- build flexible software that allows multiphysics modeling

simulation based on high end models (MHM)

Current applications

Goal: inverse problem: determine conductances by experiments (A. Leitão (UFSC), J. Mandujano Valle (LNCC)) The problem:

• consider V = F(g) where

$$c_M \frac{\partial V}{\partial t} = \epsilon \frac{\partial^2 V}{\partial x^2} - g(x)(V - E)$$

◆□▶ ◆□▶ ▲□▶ ▲□▶ ■ ののの

• find
$$g = F^{-1}(V)$$

► Landweber nonlinear: $g_{k+1} = g_k + F'(g_k) * [F(g_k) - V]$

Future

 stochastic modeling (Hugo de la Cruz Cansino (FGV), Ana Valentim (LNCC))

- domain decomposition fits very well PDE models in neuroscience, where the problem was already decomposed by nature
- the idea is to decompose a neuron into its edges, and solve one-dimensional problem in parallel
- The traditional order, discretize in time and then in space, has to be changed
- Probably the primal hybrid method (AKA MHM) beats the dual hybrid one
- the final cost might be high, depending on the number of local problems to be solved. But it's usually cheaper to solve several smaller problems than a big one (even sequentially)
