# Tralics, a LATEX to XML translator 

José Grimm<br>INRIA<br>2002, Route des Lucioles, BP 93,<br>06902 Sophia Antipolis CEDEX<br>Jose.Grimm@sophia.inria.fr<br>http://www-sop.inria.fr/miaou/Jose.Grimm

#### Abstract

In this paper we describe Tralics, a LATEX to XML translator. A previous version of the software (written in Perl) was used to obtain the Pdf version of Inria's "Rapport d'Activité" for year 2001. The current version of the software (written in $\mathrm{C}++$ ) is used for both the HTML and Pdf version for the year 2002: the XML generated by Tralics is conforming to a local DTD, similar to the TEI; it was converted to Pdf via pdfTEX and the xmltex package, and the HTML via a xslt processor.

We explain here the philosophy of the software, its usage, its limitations, and how to customize it.

## Résumé

Dans cet article nous décrivons le logiciel Tralics, un traducteur de $\mathrm{IA}_{\mathrm{E}} \mathrm{X}$ vers XML. Une version antérieure de ce logiciel, écrite en Perl, a été utilisée pour générer la version Pdf du Rapport d'activité de l'Inria en 2001. La version actuelle du logiciel, écrite en $\mathrm{C}++$, a été utilisée pour obtenir à la fois le HTML et le Pdf de la version 2002 : nous avons utilisé une DTD locale, similaire à la TEI, et pdfTEX plus xmltex pour obtenir le Pdf.

Nous expliquons ici la philosophie de Tralics, son usage, ses limitations, et comment paramétrer le logiciel.

## Introduction

If you run Tralics on a document like this one, you will get as output a document that starts and ends like this:

```
<?xml version='1.0' encoding='iso-8859-1'?>
<!DOCTYPE eurotex SYSTEM 'tugboat.dtd'>
<!-- translated from latex by tralics 1.8a-->
<eurotex language='english'>
<titlepage>
<ti>Tralics, a <LaTeX/> to XML translator</ti>
<NetA>Jose.Grimm@sophia.inria.fr</NetA>
<U>http://www-sop.inria.fr/miaou/Jose.Grimm</U>
<resume><p>
In this paper we describe Tralics,
<byear>1999</byear>
</citation>
</biblio></eurotex>
```

All that is needed for this example to work is to put, in the configuration file read by Tralics, the following lines:

```
BeginType eurotex
    DocType = eurotex tugboat.dtd
BeginTitlePage
    \maketitle <titlepage> "" ""
    \title <ti> "No title"
    \netaddress <NetA> "No address"
    \personalURL <U> "No url given"
    \resume E<resume> "Pas de résumé"
    \abstract E<abstract> "no abstract"
    \author + <author> <auth> "No authors"
    \address p<address> "no address"
End
End
```

Once you have an XML version of the document, you can use any tool you wish to process it (we used the gnome library, http://xmlsoft.org/), but something has to be done. There are typically two kinds of applications: everybody that wants to publish an Inria Technical Report has to give, together with the typeset PostScript document, the start of the $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ source, which is processed by an
ad hoc tool that adds a new item to the publication data basis. One could use Tralics to convert the partial document, and an xslt style sheet to extract from the <titlepage> element all relevant information, like name of author, title, abstract, keywords, etc. In such a situation, the presence of an unknown element like <LaTeX/> or an unexpected math formula causes no problem, the element can be replaced by its name, and the math formula removed (the current process behaves like this).

A second type of application is the following: for some reasons, the $\mathrm{IA}_{\mathrm{E}} \mathrm{C}$ document has to exists in both PostScript and HTML form, and XML is used as intermediate, common, format. In such a case there should be little difference between the PostScript as seen by the author (direct route) and the final version (the XML route). As a result, the translation of $\backslash$ LaTeX must match the IATEX logo at best, and it is not possible to reject a math formula under the pretext that it does not fit in the MathML standard. As indicated on the figure page 104 of (Carlisle, Goossens, and Rahtz, 2000), there are lots of possibilities, none of them is very simple. In practice, even more tools are needed if the objective is a complete web site.

This paper is formed of two parts: we first explain the main application of Tralics (why a new software, how it is used, what is done with the resulting XML, etc.), after that, we shall explain what Tralics does in the same order as the AT TEX companion (Goossens, Mittelbach, and Samarin, 1993).

## Why another LaTeX to $\mathbf{X}$ translator?

Inria's annual activity report has a long history, as long as the history of Inria itself. In fact, each research team has to report, each year, on its activity; this set of documents, which we call the RA in what follows, is sometimes called the scientific annexes to the annual report (which is a bilingual document on glazed paper with lots of figures and photographs, produced by a specialized company).

Since year 1987 the RA is typeset by $\mathrm{IATEX}_{\mathrm{E}} \mathrm{X}$, using a specific document style (or document class), see (Louarn, 1988). Since then, the number of pages has evolved from one thousand to three thousand, and the document is no more printed on paper (a CD-Rom version is available since 1999). On the other hand, a HTML version of the document exists since 1994, it was produced by latex2html (using SGML as intermediate language for the first year).

In the years 1997-98, some discussions showed that it would be nice to redesign the RA, using XML as intermediate language. We contacted some companies, but got no good answer: nobody was able
to translate the $\mathrm{AT}_{\mathrm{E}} \mathrm{X}$ input into an XML output, no guarantee was given about quality of a printed version of the XML, and mathematical support was very poor. These three points will be discussed later on.

These discussions were not completely negative: a new concept emerged, the RAWEB. Essentially, it is formed of "modules", that can be read independently (lots of nice properties of these modules are still to be implemented; for instance, depending on the user profile, these modules could be presented in one order or another). Each module is equivalent to a web page, and can be put in a "classeur" (French equivalent of a loose-leaf file, it's like a caddy but elements are ordered; there is no official English name for it). The objects in the caddy can be reordered, and the caddy can be transformed into a single HTML document (in 1999, the caddy contained the $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ version of the modules, hence was able to produce a PostScript document; we hope that next year it will contain the XML version of the modules, but running pdfTEX on the web server is not an option).

Moreover, the notion of a RA-conforming document was formalized (and this served as the basis of the raweb DTD), a syntax checker was written in Perl. This checker has some intrinsic limitations: since it was unaware of macro-expansion and commands like \csname, it was very easy to fool it.

## Our new translator

In fall 2001, we decided to fabricate a translator and to test it; the tool was based on ltx2x (a translator by Peter Wilson, available on CTAN) and $\Omega$ (a TEX extension that produces MathML as a byproduct, (Haralambous and Place, 1999)), together with a Perl script that was used as a syntax checker, a module splitter, and a pre- and post-processor. A second version of the tool, written entirely in Perl, was used for the Pdf version of the RA2001.

The description of the software can be found in (Grimm, 2002), together with lots of examples that could not be translated. For instance this one:
\catcode ' $\$=$ =\active $\% \$$ emacs
\def\$\#1~\{\catcode'\$=3 zut\}
\$\left[1=2\right)\$ is a formula~!
We decided to rewrite completely the software in May 2002, and to call it tralics. The previous example is understood correctly by Tralics, meaning that Tralics groks catcodes, active characters, delimited arguments, etc. More complicated is
\{\catcode'\_\active\global\let_X\}
\begingroup $\backslash$ lccode $'$ ~ $=$ '\_

## \catcode" $\backslash \sim$ active <br> \lowercase\relax\{~\def~\{u\}\endgroup ~a\}~ $\backslash$ MakeUppercase\{abAB\ae\i\}

This shows that \lowercase is fully implemented, including funny details, like the optional $\backslash$ relax before the open brace. One objective was to fully implement the $\mathrm{TEX}_{\mathrm{E}}$ macro-expansion mechanism, including conditionals (and to translate most $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ constructs). The following example provokes an error:

```
\font\foo=cmr10 scaled 1023
\setbox0=\hbox to 10pt{\foo p\hss}
\ifdim\dp0>Opt 1\else 2\fi
```

Here, the first line defines a command $\backslash f \circ o$ that selects some font; since we do not want to parse font metric files, all these fonts are equivalent and $\backslash$ foo is a no-op. The second line constructs an horizontal box and puts its content into box0; we shall explain later what Tralics does with the box. One thing is clear: the objective of Tralics is not to split a paragraph into lines, so that there is no packaging, no overfull hboxes, no underfull vboxes. In fact, the box specifications and the \hss command are ignored, the resulting box contains only the letter p. When you ask for the depth of the box, Tralics signals an error (and returns 0).

Note that \ifvmode and \ifinner are part of TEX's macroexpansion mechanism, but these commands are not implemented, mostly because there is little relationship between the modes of $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ and the modes of Tralics. All you need to know is that the following lines work as expected

```
\ensuremath{\Omega}
\leavevmode
\mbox{\par}
```

The last line is silly: inside a box, \par cannot start a new paragraph, and the resulting box is empty. For simplicity, the \par token is allowed anywhere (as if every command were prefixed with \long). Why \mbox is declared \long in LATEX is beyond me.

## The target language

The main job of a translator like Tralics is to read and analyze the input document, manage it (and simplify, complete, re-order, etc.) and produce a new document. The big question here is: what elements should be chosen? In the case of latex 2 html , the choice is limited to HTML version 2.0, 3.0, 3.2, and 4.0. In the case of Tralics, there is no predefined set of elements. In the opening example, we used <U> for the \personalURL command, in or-
der to avoid long lines, but more suggestive names should be used.

The default behavior of Tralics is defined by its main application, namely the raweb, with the following constraints: the resulting XML has to be converted to a set of HTML pages, one page for each module, it has to be converted to PostScript or Pdf, one document per research team, without loss in typographic quality, and finally, mathematics should not be forgotten. Two style sheets were used, one to produce HTML, and another one for the Pdf version. Formatting a document is not trivial, because some objects have to be evaluated more than once, sometimes depending on the context (this explains why some $\mathrm{IAT}_{\mathrm{E}} \mathrm{C}$ commands are fragile). In our case, the formatting was done by $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ or pdfTEX, which was able to parse XML files thanks to the xmltex package, see (Carlisle, Goossens, and Rahtz, 2000). There is still work to to, in particular concerning tables: the implementation of tables in fotex.sty is rather disturbing; 400 lines of $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ code were needed (for instance to patch the behavior of <mfenced> and <mover>, and to get the cover page right).

For the DTD, we first considered the Docbook DTD, (Walsh and Muelner, 1999), and discarded it, because it was too complicated. We considered then the TEI, and simplified it drastically. Lots of interesting material can be found on that web site (http://www.tei-c.org/), included PassiveTEX, (Rahtz, 2003), which is companion tool to xmltex, and a model for the above-mentioned style sheets.

On the other hand, we added some features, in order to implement figures, tables, math, etc. For obvious reasons, we use the presentation elements of MathML, (Carlisle, Ion, Miner, and Poppelier, 2001), but the design of the bibliography is not yet done (more on this subject will follow).

There are nearly one hundred elements in this DTD, 30 elements being specific to the raweb, 20 for the bibliography, other elements are borrowed from the TEI. Via the configuration file, you can change the default names (except those defined by MathML, and those specific to the raweb); using commands like \xmlelement, you can generate additional elements. If you do so, you can convince Tralics to use your own DTD. The software, the documentation, and the raweb DTD can be found on the following web site
http://www-sop.inria.fr/miaou/tralics/

## Application to the raweb

The main application of Tralics can be found on Inria's web site

## http://www.inria.fr/rapportsactivite

For year 2002, 125 teams have written their activity report, (in LATEX , with one exception) and the result is over 3000 pages of $\operatorname{Pdf}$ (A4 format, 10 point font size), resulting in 3890 HTML pages, that occupy 598.386 Mb of the CD-rom. Translating these files took 100 seconds ( 30 seconds if Tralics is compiled with the -02 switch, this shows that the C++ optimizer does a good job). The most time consuming operation was the conversion from XML to Pdf (the xmltex parser is very slow), and production of images (conversion from PostScript to Pdf via the epstopdf Perl script, and to png, using tools borrowed from latex2html).

Lots of people were involved in the process: first the raweb team, which contributed to the design of the raweb (the web site, the paper version, the idea of using XML, the DTD), the authors of the texts, the people who collected the texts and who corrected some typos, and Marie-Pierre Durollet who deserves special thanks: she wrote some shell scripts, Perl scripts, cgi scripts, part of the style sheets, etc., in fact, all that is needed to make the web site function. She was also the first real user of Tralics, in that she translated all the files, on her Linux box (other people tried Tralics on SunOS, MacOS, Windows).

One non-trivial point was the question of mathematics: there are some browsers (Amaya, Mozilla, etc), that understand MathML, or claim to do so, together with plugins and other tools supposed to visualize MathML, but we decided nevertheless to convert all the math stuff. In fact, Tralics comes with a Perl script (a bit over one thousand lines), that reads an XML file, and converts math and images.

Image post-processing Consider a simple, classical, example:

```
\begin{figure}
    \begin{center}
        \includegraphics{miaou_transf.ps}
    \end{center}
    \caption{Modèle de transducteur.}
    \label{trans}
\end{figure}
```

It is translated into

<figure file='miaou_transf' id='uid30'>
<head>Modèle de transducteur.</head>
</figure>
As can be seen, the argument of the \label command was normalized from 'trans' to 'uid30' and became an attribute of the figure element, the centering environment was ignored, the underscore treated
as a normal character, the extension of the file name was removed, and the file became an attribute of the figure element (see below an example where more than one image appears in a figure environment). The post-processing script has the charge to make sure that the image exists in PostScript, Pdf and png format. It also modifies the XML like this

```
<figure aux='image_1.png'
    file='miaou_transf' id='uid30'>
<head>Modèle de transducteur.</head>
</figure>
```

and the HTML result will be:

```
<div align="center">
    <a name="uid30"></a>
    <table>
        <caption align="bottom">
            <strong>Figure 1. </strong>
            Mod&#xe8;le de transducteur.
        </caption>
        <tr><td><img alt="miaou_transf"
                src="image_1.png"></td></tr>
    </table>
</div>
```

A few remarks are needed: the initial $\mathrm{E}^{\mathrm{A}} \mathrm{TEX}_{\mathrm{E}}$ environment is a floating one, so that the result is outside a <p> element, and using <div> for grouping is justified. The figure and its caption are centered. Note that the image is a cell of a table, because this is the easiest way to associate a caption to the table.

The è character was transformed into \&\#xe8; by an ad hoc program, because, for some unknown reasons, the style sheet refused to use latin1 encoding, it used UTF-8 instead, an encoding not understood by the program that indexes Inria's web site.

The figure was the first one in the file, so that the style sheet numbered it as figure one (in the next example, there is no \caption, hence the figure has an empty <caption>, but nevertheless a unique number). The HTML translation of \ref\{trans\} is something like <a>1</a>. The <a> element has a href attribute whose value depends on the name of the label, and the current web page, which was renamed from 'resonn', the name given by the author, to 'module 7 ', which has no meaning (searching for 'module50' on Inria's web site reveals that three teams have written at least 50 modules). The important point however is the content of the <a> element: the value 1 is not computed by Tralics, but by the style sheet.

Another example is the following.
\begin\{figure\} [htbp] }
$\backslash$ begin\{center\}
\begin\{tabular\}\{ccc\} }

```
    \includegraphics[width=3.5cm]{imgl}&
    \includegraphics[width=3.5cm]{imgc}&
    \includegraphics[width=3.5cm]{imgr}\\\
cap l&cap c&cap r
\end{tabular}
\end{center}
\end{figure}
```

The same effect could be achieved by using the subfigure environment, but we wanted to give an example of a table. Note that, if more than one image is to be put in a figure, we suggest using a table, since there are still unresolved problems regarding spacing. The translation of the previous example is the following

```
<figure rend='array' id='uid9'><p>
    <table rend='inline'> <row>
        <cell><figure file='imgl'/></cell>
        <cell><figure file='imgc'/></cell>
        <cell><figure file='imgr'/></cell>
        </row><row>
            <cell>cap l</cell>
            <cell>cap c</cell>
            <cell>cap r</cell>
    </row></table></p>
</figure>
```

In order to reduce the size, we did omit the halign $=$ center attributes for the six <cell> elements, and the width $=3.5 \mathrm{~cm}$, rend $=$ inline attributes of the three non-toplevel <figure> elements. The HTML translation is a table in a table, the inner table has no caption, the outer table has an empty caption. One of these two tables could be removed.

Math post-processing Note that a table or a figure is a float (hence is numbered) if and only if its rend attribute is not inline, on the other hand math formulas never float, but are numbered only if they are non-inline, and have a label. In what follows, we shall distinguish between the math (defined by MathML) and the formula (something we borrowed from the TEI DTD). It is the formula that has a label (hence a number), and this explains why we have some troubles translating environments like align and commands like \tag. Nevertheless, the translation of the simple formula $K \neq \Gamma$ is

```
<formula type='inline'><math><mrow>
<mi>K</mi><mo>&ne;</mo><mi>&Gamma;</mi>
</mrow></math></formula>
```

For completeness, we show here the xsl-fo stuff that is used to convert the formula into Pdf (complete code for the example above, skeleton for a displaymath formula, numbered and unnumbered).

[^0]```
    <m:mi>K</m:mi>
    <m:mo>\&\#x2260; </m:mo>
    <m:mi>\&\#x393; </m:mi>
</m:mrow></m:math>
<fotex:displaymath>
    display-math stuff
</fotex:displaymath>
<fo:inline id="uid11"><fotex:equation>
    numbered math stuff
</fotex: equation></fo:inline>
```

In this case, the Perl script that handles images and math formulas classifies the formula as a simple one, formed of three tokens in a row, a Latin letter, a symbol and a Greek letter. It replaces the formula by the following XML code.

```
<span class='math'><hi rend='it'>K</hi>
    <img src='img_other_ne.png' alt='\$\ne\$'
        width='14' height='26' align='middle'/>
    <img src='img_Gamma.png' alt='\$\Gamma\$'
        width='12' height='13' align='bottom'/>
</span>
```

Images for Greek letters and other symbols were precomputed (by latex2html). The dimensions given here are nearly twice the size of a ten-point $\neq$ and $\Gamma$, except that the depth of the $\neq$ should be 4 , and there is no way to indicate a depth in HTML. That's the reason why we indicate a total height plus depth of 26 , together with an 'align=middle' attribute. The resulting HTML is ugly (too much blank space with the line and the following one), and uses a deprecated feature, but we do not know how to do better. The resulting HTML is

```
<SPAN class="math">
<SPAN class="it">K</SPAN>
<IMG width="14" height="26" align="middle"
border="0" alt="$\ne$"
src="../images/img_other_ne.png">
<IMG width="12" height="13" align="bottom"
border="0" alt="$\Gamma$"
src="../images/img_Gamma.png"></SPAN>
```

Let's give another example: $L^{2} \rightarrow L^{\infty}$ is translated into MathML as

```
<math><mrow>
    <msup><mi>L</mi><mn>2</mn> </msup>
    <mo>&rightarrow;</mo>
    <msup><mi>L</mi><mi>&infin;</mi></msup>
</mrow></math>
```

The result here is a single image:

```
<span class='math'>
    <img align = 'bottom'
    width ='71' height ='13'
```

```
    src='math_image_1.png' border='0'
alt='Im1 \$\{L^2\rightarrow L^\infin \}\$'/>
</span>
```

A formula of the form $a^{b}$ or $a_{b}$ is considered simple (and translates to <sup> or <sub>) in the case where $b$ is an HTML character. Here, one exponent is infinity, hence an image is needed. Note how the alt field is constructed: we try to reconstruct the TEX formula from the MathML element. The first token, the Im1, indicates the image number, and is only useful for debugging. Constructing the image is not so trivial. First, a file is created that contains lines of the form

```
<formula id="1"><math><mrow>
    <msup><mi>L</mi> <mn>2</mn></msup>
    <mo>&#8594;</mo>
    <msup><mi>L</mi><mi>&#8734;</mi></msup>
</mrow></math></formula>
```

In fact, the file contains all formulas that need to be converted, with a unique id identifying the image. The xmllint processor is used to replace entity names by their Unicode values. The resulting file is processed by $\mathrm{IA}_{\mathrm{EX}}$, in the same fashion as the main document, in order to get a dvi file. The interpretation of the <formula> element (which is absent from the xsl-fo file) uses code borrowed from latex 2 html , which has two side effects. First, the log file contains a line like
12hSize :1:8.14003pt::0.0pt::48.73616pt.
and second, each page of the dvi file contains a single math formula in its upper left corner. For each such page a PostScript file is generated by dvips and it is converted to png via the pstoimg utilities, which uses the size information shown above. After a magnification factor of $40 \%$, this gives a resulting image of 13 by 71 pixels, and this information is pushed back in the XML file.

## The structure of a $\mathrm{IATEX}_{\mathrm{E}}$ document

Tralics assumes that the document to be translated conforms to IATEX standards, said otherwise that there is a line with edbysomelinescontaining\usepackagecommands,followedbyadocumentenvironment.Thisisaveryspecialenvironment,becauseitscontentisatbracelevelzero(asinstandard$\mathrm{IAT}_{\mathrm{EX}}$),andthetokensreadby$\backslash$AtBeginDocumentand$\backslash$AtEndDocumentareinsertedattherightplace,forinstance\documentclass\{article\}\usepackage\{calc\}$\backslash$AtBeginDocument\{start\}$\backslash$AtEndDocument\{end\}$\backslash$newlength$\{\backslash$foo$\}$$\backslash$AtEndDocument$\{\backslash$AtEndDocument$\{$realend$\}\}$$\backslash$begin\{document\}\setlength$\{\backslash\mathrm{foo}\}\{1\mathrm{~cm}+3\mathrm{pt}\}$\the$\backslash$foo\end\{document\}}Thislineisnottranslatedwouldproduceessentiallythefollowing<p>start31.45274ptendrealend</p>Thereisaspecialhackhere:aspecial\endinputtokenisinserted,whoseeffectistostoptranslationofthecurrentfile(afterthetokensrememberedbythedocumenthook),butthejobofthetranslatorcontinues,becauseitisatthismomentthatthebibliographyistranslated:Tralicshasthelistofall\citecommands,itcandotheequivalentofBibTEX(theresultingbibliographyisinsertedwherethe\bibliographycommandislocated).Itisanerrorifa\citecommandisseenaftertheendofthedocument(i.e.comesfroma$\mathrm{BiBT}_{\mathrm{E}}\mathrm{X}$file).undefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefinedundefined

Parameterization The first job of Tralics is to read the source file, and find a \documentclass command, in order to apply document specific rules found in the .tralics_rc file (the configuration file, it can be in the current directory or homedir). In the case where the configuration file contains

```
BeginType article
    on package loaded calc CALC = "true"
    on package loaded foo/bar FOO = "true"
End
```

then, whenever the document class is 'article' (trailing digits are ignored in the name) the two lines are executed. It follows that the root element of the resulting XML document will have the attribute CALC set to true, in case the calc package is loaded, and FOO is set to true in case the foo package is loaded with the bar option. By default, the attribute language is set (to french or english), in case Tralics is able to determine the main language, either because (as in this document), english is an option to \documentclass, or because the babel package is loaded with recognized parameters. Finally, the meaning of \setlength depends on whether the calc package is loaded or not.
Sectioning Commands The XML model of Tralics is based on the notion of paragraph ( $\backslash$ par command, <p> element). This element can contain inline stuff (text, images, tables, math formulas), it is at the same level as non-inline stuff (images, tables, math, notes, bibliographic entries), and can be contained in a sectioning command (for instance the
paragraph is in a subsection in a section in a chapter in a part). These elements have in general a number (computed by an external program rather than defined by the user, never computed by Tralics), and can be referenced. The translation of a sectioning command is a <divi> element, where $i$ is an integer between 0 and 6 . Example:

```
\section{x}A\label{a}
\subsection{y}
B\label{b}C\label{c}D
\paragraph{z}
\ref{a}\ref{b}
\subsection{t}
gives
<div0 id='uid1'><head>x</head>
    <p>A</p>
    <div1 id='uid2'><head>y</head>
        <p>BCD</p>
        <div3 id='uid3'><head>z</head>
            <p><ref target='uid1'/>
                    <ref target='uid2'/></p>
        </div3>
    </div1>
    <div1 id='uid4'><head>t</head>...
```

By default, \section is the top-level division, but chapters are allowed in a report, and parts in a book. The '. . .' is not part of the output, it just indicates the current position in the XML tree. Note that Tralics is in outer vertical mode, said otherwise, the occurrence of a character will imply the creation of a <p> element; in $I^{A} T_{E} X$, the current mode would depend on the document class. This is one reason why \ifvmode is not implemented. The example shows a logical error: there is a <div3> element in a <div1> element. It would be numbered 1.1.0.1 in ${ }^{\mathrm{LA}} \mathrm{T}_{\mathrm{E}} \mathrm{X}$, and 1.1.1 (without the zeros) using an xslt processor.

Cross references Tralics implements \label and $\backslash r e f$ but not \pageref. The basic idea is to put a mark in the XML document, and use references to this mark. The mark is an attribute of type ID, and there are some limitations in XML that do not exist in $\mathrm{IATEX}_{\mathrm{E}}$ (for instance no element type may have more than one ID attribute specified, and an ID cannot start with a digit). In order to remove these difficulties, Tralics uses its own list of IDs (uid1, uid2, etc.) Associated to the mark is a value, produced by $\backslash p @ f o o \backslash t h e f o o$. This mechanism is not implemented in Tralics: the value associated to a label is not in the XML document but must be computed by the application (the style sheet for instance). In order to distinguish between Figure 4 or Table 5, the label must be associated to a figure or a table
(a footnote, an item in a list, a formula, a division, that's all). Hence the following changes with $\mathrm{IA}_{\mathrm{E}} \mathrm{X}$ : inside a figure or table environment, there must be at most one label, and it can be before or after the caption. A math formula can have a label only if it is a display math equation, and it is numbered only if it has a label. See example above. There is no need to call Tralics twice or more: a single pass is enough.

References to external documents are understood. In the following example, we switch to French in order to show the behavior of special characters (like colon and underscore) with or without the \url command:
\language=1
\href\{http://foo\_ba\}\{http://foo_bar\}
\href\{\url\{http://foo_ba\}\}\{http://foo_bar\}
The translation is

```
<xref url='http://foo_bar'>
    http&nbsp;://foo_ba</xref>
<xref url='http://foo_bar'>http://foo_ba
</xref>
```

## Basic formatting tools

The following example is from (Knuth, 1984) page 218, with an addition to verify that the number of calls of \trialdivision is really 132.
\tracingall
\countdef $\backslash t d 4$ \td=0
\newif $\backslash i f p r i m e ~ \ n e w i f \backslash i f u n k n o w n ~$
\newcount $\backslash n \backslash$ newcount $\backslash p$ newcount $\backslash d$
\newcount $\backslash a$
$\backslash$ def $\backslash$ primes\#1 $\{2, \sim 3 \%$ assume that \#1 >= 3
\n=\#1 \advance\n by-2 $\%$ n more to go
$\backslash \mathrm{p}=5 \%$ odd primes starting with p
\loop\ifnum $\ n>0$ \printifprime
\advance\p by2 \repeat\}
\def\printp\{, \%
\ifnum $\backslash n=1$ and $\sim$ fi $\%$
\number $\backslash p$ \advance $\backslash n$ by -1 \}
$\backslash$ def $\backslash$ printifprime $\{\backslash$ testprimality
\ifprime\printp\fi\}
$\backslash$ def $\backslash$ testprimality $\{\{\backslash d=3 \backslash g l o b a l \backslash p r i m e t r u e$
\loop\trialdivision
\ifunknown\advance\d by2 \repeat\}\}
$\backslash d e f \backslash t r i a l d i v i s i o n\{\backslash a=\backslash p$
\global \advance $\backslash t d$ by 1
$\backslash d i v i d e \backslash a ~ b y \backslash d$
\ifnum\a>\d \unknowntrue\else\unknownfalse\fi
\multiply $\backslash$ a by $\backslash$ d
\ifnum $\backslash a=\backslash p$ \global $\backslash p r i m e f a l s e$ \unknownfalse\fi\}

The first thirty prime numbers are $\backslash$ primes\{30\}.
trialdivision macro was expanded \the\td $\backslash$ times

This example works in $\mathrm{AT}_{\mathrm{EX}}$ and in Tralics. All TEX primitives that start with 'tracing' are implemented, most of them refer to behavior that is not implemented in Tralics. If you run Tralics on the previous example, the $\log$ file will contain:

```
[706] \countdef\td 4 \td=0
{\countdef}
+scanint for \countdef->4
{\td}
+scanint for \td->0
[709] \newcount\a
{\countdef \a=1550}
```

You can see the input source line whenever it is read, with its line number, and the commands that are evaluated. In the $\mathrm{T}_{\mathrm{E}} \mathrm{Xbook}$ page 269 , you can see the definition of an integer. This is so complicated that Tralics prints the value whenever scanned. The last line shows that the \a command will access the internal tables at position 1550 .

```
\iterate->\ifnum \n >0 \printifprime
    \advance \p by2 \relax \expandafter
    \iterate \fi
+\ifnum
+scanint for \ifnum->28
+scanint for \ifnum->0
+iftest true
```

Here we can see that the \loop macro is implemented as in $\mathrm{EA}_{\mathrm{E}} \mathrm{X}$ and not as in plain $\mathrm{T}_{\mathrm{E}} \mathrm{X}$. The \iterate token is a private one, the \loop macro does not kill your command (but the loop inside the loop will modify it, and this explains why extra braces are needed).

```
{begin group character}
+stack: level + 2
```

The first line indicates that Tralics has seen an open brace (technically, a character of catcode one), and that it creates a new frame on the save stack (the outer level is numbered 1 , as in $\mathrm{T}_{\mathrm{E}} \mathrm{X}$.

```
{end group character}
{Text:, 5}
+stack: restoring \ifunknown
+stack: restoring integer value 1550 0
+stack: restoring \iterate
+stack: restoring integer value 1549 0
+stack: level - 2
```

And this is done when Tralics sees the closing brace. It restores two commands and the two registers $\backslash$ a and $\backslash d$ (the association between $\backslash d$ and the number 1549 can be found in the $\log$ file). A side effect of seeing the closing brace is to flush the XML buffer (what follows the 'Text:' on the second line), for the case where the current font might change.

List structures Standard IATEX lists are implemented, they are not customizable. The only non trivial part is that the optional argument of the - command should be evaluated in a group. As an example:

```
\begin{itemize}
    \item a
    \item [\it b] c
    \begin{enumerate}
        \item d
        \begin{description}
            \item e
        \end{description}
    \end{enumerate}
\end{itemize}
            This will translate to
<list type='simple'>
    <item id='uid14'><p>a</p></item>
    <label><hi rend='it'>b</hi></label>
    <item id='uid15'>
        <p>c</p>
        <list type='ordered'>
            <item id='uid16'><p>d</p>
            <list type='description'>
            <item id='uid17'><p>e</p>
            </item>
            </list>
        </item>
        </list>
    </item>
</list>
```

Note: in order to make the XML output more readable, we added and removed some space and newline tokens. The general rule for Tralics is to output one space (or newline character), whenever $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ would output one space character. In particular, the $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ scanner converts two consecutive newline characters in a space character and a $\backslash$ par token. This space character will be output by Tralics as a newline character.
Notes The translation of
$\backslash$ footnote\{a\}
\footnote\{Y \AddAttToLast\{x\}\{y\}b\par
$\backslash$ AddAttToCurrent*\{place\}\{here\}c\}
is
<note id='uid14' place='foot'>a</note>
<note place='here' id='uid15'>
<p x='y'>Y b</p>
<p>c</p>
</note>
Two remarks: each note has an uid, hence can be referenced, but there is nothing special about it (no
counter, no mark, no restrictions). On the other hand, the example shows how to add an attribute to an XML element, either the element created latest (here the <p> element that contains the text of the footnote), or the current element (the footnote, since the translation of \par does not create a new <p> element, it is the translation of the character c that forces a second <p> in the note). In the unlikely event that the element has already an attribute of the same name (for instance, a footnote has a default place attribute), the command is ignored, unless you use its starred form to overwrite.

New elements It is easy to use new elements, just say
\begin\{xmlelement\}\{main-elt\} }
\begin\{xmlelement\}\{sub-elt1\} }
text1
\end\{xmlelement\} }
\begin\{xmlelement\}\{sub-elt2\} }
text2
\end\{xmlelement\} }
\AddAttToLast\{sb2-att\}\{value1\}
\AddAttToCurrent\{foo-att\}\{att-value''\}
\end\{xmlelement\} }
and you will get

```
<main-elt foo-att='att-value&apos;&apos;'>
<sub-elt1>
text1
</sub-elt1>
<sub-elt2 sb2-att='value1'>
text2
</sub-elt2>
</main-elt>
You can also try
\hbox\{a\it b\}
\vbox\{c\it d\}
\newcommand \(\backslash\) AGtest\{AG\}
\(\backslash\) setbox \(0=\backslash\) xbox \(\{\) myelt \(\}\)
\(\{\backslash\) aftergroup \(\backslash\) AGtest \(e \backslash i t \mathrm{f}\}\)
\copy0 \copy0
```

This will work in Tralics, since an \hbox and a \vbox is just an unnamed \xbox. The braces serve for grouping, and as argument delimiters. The result is

```
a<hi rend='it'>b</hi>
c<hi rend='it'>d</hi>
AG
<myelt>e<hi rend='it'>f</hi></myelt>
<myelt>e<hi rend='it'>f</hi></myelt></p>
```

Note: when Tralics constructs a element, the equivalent of a box in $T_{E} X$, it is a special mode, that does not match any of TEX's modes.

Verbatim material A document like this one uses lots of verbatim material, hence Tralics is familiar with standard verbatim environments, and some extensions. For instance, the translation of
\DefineShortVerb\{\|\}
you can say $\mid \backslash f o o l$ or $\backslash v e r b *+f o o$ bar+.
\begin\{Verbatim\} }
verb line1
\$<\& \>
\end\{Verbatim\} }
would be

```
you can say <hi rend='tt'>\foo</hi>
or <hi rend='tt'>foo&blank;bar</hi>.</p>
<p noindent='true'><hi rend='tt'>
        verb&nbsp;line1</hi></p>
<p noindent='true'><hi rend='tt'>
    $&lt;&amp;\&gt;</hi></p>
<p noindent='true'>
```

Note that here the \end commands checks whether the environment is followed by an empty line. If it is not, a \noindent token is inserted.

## The layout of the page

The essential idea of Tralics is that the result of the translation is independent of the layout of the page.

But if you give $0.8 \backslash$ textwidth as the width of a figure, Tralics will replace this by 12 cm , because something has to be done. Optional arguments of sectioning commands are ignored: in general one would use then for marking the document. We have implemented the $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ marking commands, but they do nothing; we think of extending the functionalities of the title-page mechanism of Tralics. In fact, if the title-page specifies something like:

## \address p<address> "no address"

(see opening example), then there is a command \address, that takes one argument, whose translation is put in <address> element, and recorded. The 'p' marker says that paragraphs are allowed, an ' $E$ ' marker indicates that the command is an environment, a ' + ' that the command can be issued more than once, etc. As you can see, there is still work to be done.

## Tabular material

There are essentially four points to be considered: tables in math mode, (described later), standard LATEX tabular (see earlier example), the tabbing environment (not implemented, because it implies to implement all packages that typeset algorithms), the \halign primitive, which is much too complicated to implement.

One problem is, given the table specification $r \| l$, how to translate it. Tralics understands that there are two columns, right and left justified, with a rule on the right and the left, but this is impossible to translate into HTML, that knows only $|r| l \mid$ or rl. The \hline and \cline are implemented, but suffer from the same limitations.

## Mastering floats

There is in general enough flexibility for adding or removing one line on the current page, so that, for instance, $\mathrm{T}_{\mathrm{E} X}$ is not faced to the dilemma of either putting a section title at the bottom of a page, or generating an awfully bad underfull page. The situation is quite different for tables or images, which can be much larger, and this is the reason why they can float (i.e. items are put in the output in a different order). Handling of floats is non-trivial, in some cases, the best thing to do is to resize (the image, or even the text).

The philosophy of Tralics is the following: in the case where the XML is translated into HTML, no object has to float. On the other hand, since the author of the document is not the person that does the final typesetting, no fine tuning of floats can be achieved. As a result, Tralics just ignores optional arguments of float environments, float parameters, and things like wrapfig environments.

## Font selection

The introductory example shows some features of Tralics. For instance, the default input encoding of the document is latin1, and this is the same as the output encoding: the translation of éloe will be é\œ you can also say \'e\.E if you want éÉ; all Unicode characters with code less than x180 are recognized. If you need other characters, you must use a construct like

## Hàn Th $\backslash x m l l a t e x\{\& \backslash \# x 1 e b f ;\}\{\backslash ’\{\backslash へ e\}\}$ Thành

The command \xmllatex takes two arguments, the first one is ignored by standard $\mathrm{LA}_{\mathrm{EX}}$, and the second one by Tralics. Note how the sharp sign is protected. See the Unicode manual (The Unicode Consortium, 2000) for the numeric value 'x1ebf'. There is no way to construct a logo, like the $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ logo, with \kern or \lower, but instead, you could say
\newcommand $\backslash$ MyLogo $\backslash$ xmlemptyelt\{MyLogo\}\}
and define a <MyLogo/> element in your DTD. You could also use a parameterized version of the logo, like this
\newcommand $\backslash$ ParLogo [1] \{\xmlelt\{PLogo\}\{\#1\}\} $\backslash$ MyLogo
\ParLogo\{2\$\varepsilon\$\}

The resulting XML document will contain

## <MyLogo/>

<PLogo>2<formula type='inline'><math>
<mi>\&epsiv;</mi></math></formula></PLogo>
As explained above, Tralics knows of the \font command, but this command should not be used. It is much better to say something like
$\{\backslash$ bfseries $a \backslash i t s h a p e ~ b \backslash s m a l l ~ c \backslash t t f a m i l y ~ d\}$ which translates into:

```
<hi rend='bold'>a</hi>
<hi rend='it'><hi rend='bold'>b</hi></hi>
<hi rend='small'><hi rend='it'>
    <hi rend='bold'>c</hi></hi></hi>
<hi rend='small'><hi rend='it'>
    <hi rend='tt'><hi rend='bold'>d</hi>
</hi></hi></hi>
```

As this example shows, a font is defined by a size, shape, series and family, nothing more (is it possible to put convert to HTML a document written in Computer Modern Funny Roman using the U encoding?) Tralics understands all ten standard font sizes, but uses only three (a normal size, a larger one, and a smaller one); there are some bugs in the implementation. In an example like this
\{\it a\par b\}
a new paragraph is created when the $b$ character is sensed, and a font element must be inserted in this paragraph, since the current font is not the default one. The commands \it, \textit, \itshape have the same meaning as in $\mathrm{IAT}_{\mathrm{E} X}$. The $\backslash e m$ command also (but Tralics does not know if the current font is slanted or not, and may generate the wrong result).

## Higher mathematics

TEX has a reputation of producing very high quality mathematics, and people at the AMS have worked hard to make it easy to use. As a result, trying to translate the whole AMS stuff to MathML is nearly impossible (too many features have no equivalent); on the other hand, converting the MathML into Pdf was a challenge (there are still unresolved problem, like tables in tables, missing characters, etc.), and the rendering by tools like Amaya were a bit strange.

The translation of $\int_{0}^{\infty} \mathcal{F}(x)^{2} \mathrm{~d} x$ is unsatisfactory to us. In particular, Tralics fails to notice that the exponent applies to the ' $\mathcal{F}(x)$ ', and we wonder whether an expert system should be used (consider the scope of the <mrow> element in the translation below).

```
<math>
    <mrow>
    <msubsup><mo>&int;</mo>
```

```
        <mn>0</mn> <mi>&infin;</mi>
    </msubsup>
    <mrow><mi>&Fscr;</mi><mo>(</mo>
        <mi>x</mi> </mrow>
    <msup><mo>)</mo><mn>2</mn> </msup>
    <mspace width='3pt'/><mi> d </mi>
    <mi>x</mi>
</mrow></math>
```

## IATEX in a multilingual environment

Inria's Rapport d'Activité is, by nature and law, a French document. The RA, or the RAWEB, being just its scientific annex, can be in English (with a French summary). It was decided that next year (i.e year 2003), the whole thing (the source document, the web site, the logo, the these-pages-in-Frenchonly pointers) will be in English. Thus a special attention was given to this problem in Tralics. For instance, whether the title of the bibliography should be "References" or "Références" does not depend on Tralics, but on the style sheet (or the DTD). On the other hand, one may imagine a document (like this one) that has an abstract in two languages, and that the first abstract should be in the main language. Using the title page mechanism of Tralics will give you a fixed order for the XML result, but as the introductory example shows, the main language is an attribute of the root element (and it is the \maketitle command that selects the current language as main language).

In fact, $\mathrm{T}_{\mathrm{E}} \mathrm{X}$ provides a \setlanguage command, which is ignored by Tralics, and a \language command that selects a language: Tralics assumes that English has number zero, French has number one, and your favorite language has number two (in fact, only two languages are really supported). The BibTEX translator (see below) uses the value of the current language for the interpretation of strings like 'jan'. The following example shows the differences between French and English:
\language =1
<<guill'' ponctuation;
\verb+<<guill', ponctuation;+
a\xspace b\xspace !
$\backslash$ language $=0$
<<guill', ponctuation;
a\xspace b\xspace !
The translation is
<\ guill\ » ponctuation\  ;
<hi rend='tt'>\<\<guill
'\​'\​ \  ponctuation;</hi>
a b\ !

```
<&nbsp;guill', ponctuation;
a b!
```

The important points are the following: a space is added before some punctuation characters (colon, semi-colon, guillemets, etc), even when the xspace package (language independent) thinks it useless. Everything that looks like opening or closing double quotes are converted to French guillemets, with the proper spacing. Note the translation of the \verb command: the two single quotes are followed by a special (invisible) character, the purpose of which is to avoid ligatures in the case where the XML is processed by $\mathrm{T}_{\mathrm{E}} \mathrm{X}$; the line breaks were manually added in order to avoid overfull lines.

## Portable graphics in EATEX

We tried to implement some commands, for instance
\setlength\{\unitlength\}\{.0075\textwidth\}
\begin\{picture\} } ( 9 0 , 5 0 )
\put $(40,25)\{\backslash$ framebox $(10,10)\{\$ \mathrm{H}(\mathrm{s}) \$\}\}$
\put $(19,30)\{\backslash$ vector $(1,0)\{9\}\}$
$\backslash \operatorname{put}(60,15)\{\backslash$ vector $(-1,0)\{10\}\}$
$\backslash$ put $(17.75,0.5)\{\backslash$ oval $(1.5,1.5)[r]\}$
\end\{picture\} }
The result is given below. However, for the RA, we copied the content of the picture environment in a file, called $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ on it, and replaced the picture by a reference to the PostScript file.

```
<picture width='90.Opt' height='50.Opt'>
<put xpos='40.0pt' ypos='25.0pt'>
    <box width='10.0pt' height='10.0pt'>
    <formula type='inline'><math>
        <mrow><mi>H</mi><mo>(</mo><mi>s</mi>
        <mo>)</mo></mrow></math>
    </formula></box></put>
<put xpos='19.0pt' ypos='30.0pt'>
    <vector xdir='1.0pt' ydir='0.0pt'
        width='9.0pt'/></put>
<put xpos='60.0pt' ypos='15.0pt'>
        <vector xdir='-1.0pt' ydir='0.0pt
        width='10.0pt'/></put>
<put xpos='17.75pt' ypos='0.5pt'>
        <oval xpos='1.5pt' ypos='1.5pt'
        specs='r'/></put>
</picture>
```

## Using PostScript

Since our main application uses Pdf in preference of PostScript, we will not speak about PostScript here (some people use psfrags in order to replace PostScript fonts in their figures by standard $\mathrm{IA}_{\mathrm{E}} \mathrm{X}$ ones, this is strange).

## Index generation

Tralics offers no specific tool.

## Bibliography generation

The design of the bibliography of the raweb is still a subject of research. We were faced to the following problems: first, the raweb uses three different $\mathrm{BibT}_{\mathrm{E}} \mathrm{X}$ files, and the translation of one these files depends on whether it was put on the web or printed on paper, and the items in the main bibliography file are to grouped in different categories, depending on their type; a total of four bst files are used. One idea was to parse the bbl files (but, if you look at the sources of the footbib package, you can see how hard it is; by the way, bibliographic entries are no more footnotes). The second idea was to modify the bst file in order to generate an environment per item, in order to simplify the parsing. The third idea was to abandon BibTEX; since there is still no XML standard for bibliography, and no universal tools, we just wrote a BibTEX to $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ translator. For instance, the $\mathrm{T}_{\mathrm{E}} \mathrm{Xbook}$ entry looks like this
\citation\{Knu84\}\{cite:texbook\}\{year\}\{book\}
\bauteurs\{\bpers\{D. E. $\}$ \{\}\{Knuth\}\{\}\}
\cititem\{btitle\}\{The \TeX book\}
\cititem\{bpublisher\}\{Addison Wesley\}
\cititem\{byear\}\{1984\}
\endcitation
This part of the translator reads the $\mathrm{BibT}_{\mathrm{E}} \mathrm{X}$ file, expands the $\mathrm{BiBT}_{\mathrm{E}} \mathrm{X}$ macros (predefined, or used defined), removes useless stuff, sorts the entries, and returns the $\mathrm{IAT}_{\mathrm{E}} \mathrm{X}$ equivalent (in fact, the stuff is written in a bbl file, but only for you to see what happens in case of error). The same entry processed by BibTEX:

```
\bibitem[\protect\citeauthoryear{Knuth}
{Knuth}{1984}]{texbook}
Knuth, D.~E.
\newblock {\em The \TeX book}.
\newblock Addison Wesley, 1984
\UseExtraLabel{}.
```

A comparison shows that BiBTEX adds some tokens that would be very hard to remove: tilda, comma, period, together with some others (\em, \newblock) that can be context sensitive. On the other hand, the LATEX to XML translator generates

```
<citation from='year' key='Knu84'
    id='cite:texbook' type='book'>
<bauteurs>
    <bpers prenom='D. E.' nom='Knuth'/>
    </bauteurs>
    <btitle>The <TeX/>book</btitle>
```

## <bpublisher>Addison Wesley</bpublisher> <byear>1984</byear> <br> </citation>

so that it is up to the style sheet to do all the real work (like: using \em for the title if it's a book, use the plural of 'editor' if there is more than on). Each style has it own specificities: the tugboat style generates a special optional argument for \bibitem, but the raweb tools need the from and type attributes for sorting (problem here: citations are already sorted).

## Conclusion

We have showed in this paper that a $\mathrm{EA}_{\mathrm{E}} \mathrm{X}$ to XML translator can be very useful, whenever you have the tools to manage the resulting XML. We hope that standardization will continue, so that it will become easier to write such tools, and adapt them. Putting high quality mathematics on the web is still a challenge, and we hope that people will appreciate our contribution.
