Propagation

Computation of  
the threshold

$B \geq 2$

Questions

## Arrival

- Customers arrive to an infinite-buffer queue.
- Time is discrete.
- The distribution of arrivals in each slot  $A_t$ , arbitrary with mean  $\lambda$  (customers/slot)

# The Model

## Scheduling with Impatience

Jean-Marie & Hyon

$B = 1$

Results

Propagation

Computation of  
the threshold

$B \geq 2$

Questions

## Services

- Service occurs by *batches* of size  $B$ .
- Service time is one slot.

# The Model

## Deadline

Customers are *impatient*: they may leave before service.

- the individual probability of being impatient in each slot:  $\alpha$
- memoryless, **geometrically distributed** patience

Scheduling

Computation of

the threshold

$B \geq 2$

Questions

# The Model

## Control

Service is *controlled*.

- The controller knows the number of customers but not their amount of patience: just the distribution.
- It decides whether to serve a batch or not.

$B \geq 2$

Questions

# The Question

What is the optimal *policy*  $\pi^*$  of the controller, so as to minimize the  $\theta$ -discounted global cost:

$$v_{\theta}^{\pi}(x) = \mathbb{E}_x^{\pi} \left[ \sum_{n=0}^{\infty} \theta^n c(x_n, q_n) \right],$$

where:

- $x_n$ : number of customers at step  $n$ ;
- $q_n$ : decision taken at step  $n$ ;

and  $c(x, q)$  is the cost incurred, involving:

- $c_B$ : cost for serving a batch (*setup cost*)
- $c_H$ : per capita *holding cost* of customers
- $c_L$ : per capita *loss cost* of impatient customers.

The Literature  
This talk

Dynamic  
Programming  
representation

$B = 1$

Results  
Propagation  
Computation of  
the threshold

$B \geq 2$

Questions

The sequence of events leads to :

$$x_{n+1} = S([x_n - q_n B]^+) + A_{n+1} .$$

$S(x)$ : the (random) number of “survivors” after impatience, out of  $x$  customers initially present.

$I(x)$ : the number of impatient customers.

$\implies$  binomially distributed random variables

# Costs

The cost at step  $n$  is:

$$c_B q_n + c_L I([x_n - q_n B]^+) + c_H [x_n - q_n B]^+$$

## Average Cost

$$c(x, q) = q c_B + (c_L \alpha + c_H) (x - qB)^+ = q c_B + c_Q (x - qB)^+ .$$

Optimization criterion:

$$v_{\theta}^{\pi}(x) = \mathbb{E}_x^{\pi} \left[ \sum_{n=0}^{\infty} \theta^n c(x_n, q_n) \right] .$$

Questions

# Dynamic programming equation

The optimal *value function*  $V(x)$  is solution to:

## The dynamic programming equation

$$V(x) = \min_{q \in \{0,1\}} \{c_B q + c_Q [x - Bq]^+ + \theta \mathbb{E} (V(S([x - Bq]^+) + A))\}.$$

The optimal policy is *Markovian* and feedback: there exists a function of the state  $x$ ,  $d(x)$ , such that

$$\pi^* = (d, d, \dots, d, \dots)$$

and  $d(x)$  is given by:

## The optimal policy

$$d(x) = \arg \min_{q \in \{0,1\}} \{\dots\}.$$

Questions

## Theorem

*The optimal policy is of threshold type: there exists a  $\nu$  such that  $d(x) = 1_{\{x \geq \nu\}}$ .*

## Theorem

*Let  $\psi$  be the number defined by*

$$\psi = c_B - \frac{c_Q}{1 - \bar{\alpha}\theta}.$$

*Then,*

- 1 *If  $\psi > 0$ , the optimal threshold is  $\nu = +\infty$ .*
- 2 *If  $\psi < 0$ , the optimal threshold is  $\nu = 1$ .*
- 3 *If  $\psi = 0$ , any threshold  $\nu \geq 1$  gives the same value.*

# Method of Proof

Framework: propagation of properties through the dynamic programming operator (Puterman, Glasserman & Yao).

## Requirement 1

$$\exists w(\cdot) \geq 0, \quad \sup_{(x,q)} \frac{|c(x,q)|}{w(x)} < +\infty,$$

$$\sup_{(x,q)} \frac{1}{w(x)} \sum_y \mathbb{P}(y|x,q) w(y) < +\infty,$$

and  $\forall \mu, 0 \leq \mu < 1, \exists \eta, 0 \leq \eta < 1, \exists J$ , such that:  $\forall J$ -uple of Markov Deterministic decision rules  $\pi = (d_1, \dots, d_J)$ , and  $\forall x$ ,

$$\mu^J \sum_y P_\pi(y|x) w(y) \leq \eta w(x).$$

→ works with  $w(x) = C + c_Q x$

Questions

# Method of Proof

Framework: propagation of properties through the dynamic programming operator (Puterman, Glasserman & Yao).

## Requirement 2

$\exists V^\sigma, \mathcal{D}^\sigma$

- 1  $v \in V^\sigma$  implies  $Lv \in V^\sigma$ ,
- 2  $v \in V^\sigma$  implies there exists a decision  $d$  such that  $d \in \mathcal{D}^\sigma \cap \arg \min_d L_d v$ ,
- 3  $V^\sigma$  is a closed by simple convergence.

→ works with:

$V^\sigma = \{ \text{increasing and convex} \}$  and

$\mathcal{D}^\sigma = \{ \text{monotone controls} \}$

Questions

# Propagation of structure

## Theorem

Let, for any function  $v$ ,  $\tilde{v}(x) = \min_q Tv(x, q)$ . Then:

- 1 If  $v$  increasing, then  $\tilde{v}$  increasing
- 2 If  $v$  increasing and convex, then  $\tilde{v}$  increasing convex

## Theorem

If  $v$  is increasing and convex, then  $Tv(x, q)$  is submodular over  $\mathbb{N} \times \mathcal{Q}$ . As a consequence,  $x \mapsto \arg \min_q Tv(x, q)$  is increasing.

## Submodularity (Topkis, Glasserman & Yao, Puterman)

$g$  submodular if, for any  $\bar{x} \geq \underline{x} \in \mathcal{X}$  and any  $\bar{q} \geq \underline{q} \in \mathcal{Q}$ :

$$g(\bar{x}, \bar{q}) - g(\underline{x}, \bar{q}) \leq g(\bar{x}, \underline{q}) - g(\underline{x}, \underline{q}).$$

Questions

The system under threshold  $\nu$  evolves as:

$$x_{n+1} = R_\nu(x_n) := S([x_n - 1_{\{x \geq \nu\}}]^+) + A_{n+1} .$$

A direct computation gives:

$$V_\nu(x) = \frac{c_Q}{1 - \theta\bar{\alpha}} \left( x + \frac{\theta\lambda}{1 - \theta} \right) + \psi \Phi(\nu, x)$$
$$\Phi(\nu, x) = \sum_{n=0}^{\infty} \theta^n \mathbb{P}(R_\nu^{(n)}(x) \geq \nu)$$
$$\psi = c_B - \frac{c_Q}{1 - \bar{\alpha}\theta} .$$

$B \geq 2$

Questions

## Lemma

*The function  $\Phi(\nu, x)$  is decreasing in  $\nu \geq 1$ , for every  $x$ .*

Proof by a coupling argument. If  $O_\nu^{(n)}$  = set of customers present at time  $n$  under threshold  $\nu$ , starting from  $x_0 = x$ :

## Lemma

*For every trajectory, we have*

$$O_{\nu+1}^{(n)} = \begin{cases} \text{either } O_\nu^{(n)} \\ \text{or } O_\nu^{(n)} \cup \{j_n\} \end{cases}$$

*where  $j_n$  is the customer of smaller index in  $O_{\nu+1}^{(n)}$ .*

$$\implies \left\{ R_{\nu+1}^{(n)}(x) \geq \nu + 1 \right\} \subset \left\{ R_\nu^{(n)}(x) \geq \nu \right\} .$$

# What goes wrong when $B \geq 2$

Numerical experiments and exact results in special cases reveal that:

- The value function  $V(x)$  is not convex in general
- The function  $TV(x, q)$  is not submodular in general

Examples with  $B = 10$ ,  $\alpha = 1/10$ ,  $\theta = 8/10$ :  $V$  not convex

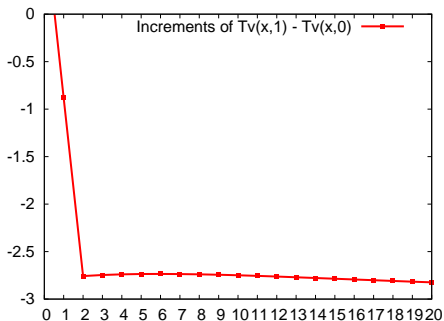

# What goes wrong when $B \geq 2$ , ctd.

Submodularity: if  $Tv(x, 1)$  is submodular, then  $x \mapsto Tv(x, 1) - Tv(x, 0)$  is decreasing.

A counterexample with  $B = 2$ ,  $\lambda = 1/10$ ,  $\alpha = 9/10$ ,  $\theta = 9/10$ .

Papadaki & Powell study the same problem without impatience.

## Dynamics without impatience

$$x_{n+1} = [x_n - q_n B]^+ + A_{n+1} .$$

They show that the following “K-convexity” propagates:

## K-convexity

$$V(x + K) - V(x) \geq V(x - 1 + K) - V(x - 1) .$$

Also used in Altman & Koole for batch arrivals.

$\implies$  does not work here.

Koole (2006) and Koçağa & Ward (2009) mention the incompatibility of impatience with structure theorems.
