Origin of the problem: the VoDDnet (a.k.a. “Peerates”) company.

Distributed Storage and Download System:

- many storage sites, each with limited capacity
- potentially unavailable
- existence of a permanent backup data storage

Among the design issues for such a system

- how much replication of the data?
- where to place it?
- what download strategy?

We fix a particular download strategy. We consider the download time as the metric of interest.

- 1 Documents with different popularity:
how much replication of the data?
→ combinatorial optimization problem
- 2 Documents with identical popularity:
where to place the replications?
 - theoretical properties
 - experimental investigation

Document model:

- K distinct documents
- p_k , popularity (probability) of document k
- T_k , number of unit-size blocks of data in document k
- r_k , replication factor for document k (same for every block)
- bound N on the replication number

Network/Storage Assumptions:

- sites available with uniform probability δ , independently
- download from distributed sites (“clients”) at data rate θ_c (blocks/s)
- download from central server at data rate θ_s (blocks/s)
- global storage capacity S

Availability

One block is available if at least one of its replications is online:

$$P(\text{block available}) = 1 - (1 - \delta)^{r_k} = 1 - \gamma^{r_k} .$$

Let Λ_k be the number of available blocks in the document:

Document Availability

Λ_k is a Binomial Random Variable with parameters T_k and $1 - \gamma^{r_k}$. In particular

$$\begin{aligned}\mathbb{E}\Lambda_k &= T_k (1 - \gamma^{r_k}) \\ \mathbb{E}(T_k - \Lambda_k) &= T_k \gamma^{r_k} .\end{aligned}$$

Response time

Individual response time

Response time for document k

$$R_k = \frac{\Lambda_k}{\theta_c} + \frac{T_k - \Lambda_k}{\theta_s}$$

Average response time

Taking into account popularity

$$\begin{aligned}\mathbb{E}R &= \sum_{k=1}^K p_k \mathbb{E}R_k \\ &= \frac{1}{\theta_c} \sum_k p_k T_k + \left(\frac{1}{\theta_s} - \frac{1}{\theta_c}\right) \sum_k p_k T_k \gamma^{r_k} .\end{aligned}$$

Optimization problem

Minimizing the expected download time:

Minimum download time

$$\begin{aligned} \min_{r_k} \quad & \sum_k p_k T_k \gamma^{r_k}, \\ \text{subject to} \quad & \sum_{k=1}^K T_k r_k \leq S \\ & \text{and } 0 \leq r_k \leq N \text{ for all } k, \end{aligned}$$

where $\gamma \in [0, 1]$, $0 \leq p_k \leq 1$, $T_k \geq 0$, $\forall k$.

In the relaxation of the problem, $r_k \in [0, N]$. In the real problem, $r_k \in [0..N]$.

Algorithmic Complexity

Limiting cases are difficult problems:

$\gamma \sim 0$ In that case, $r_k \in \{0, 1\}$ and $\gamma^{r_k} \sim 1 - r_k$.

Knapsack problem

$$\min_{r_k} \sum_k p_k T_k (1 - r_k) \quad \text{s.c.} \sum_{k=1}^K T_k r_k \leq S$$

and $r_k \in \{0, 1\}$ for all k .

$\gamma \sim 1$ In that case, $\gamma^{r_k} \sim 1 - \delta r_k$.

Bounded knapsack problem

$$\min_{r_k} \sum_k p_k T_k (1 - \gamma r_k) \quad \text{s.c.} \sum_{k=1}^K T_k r_k \leq S$$

and $r_k \in \{0, \dots, N\}$ for all k .

Lagrangian formulation

Lagrangian:

$$L(r_k, \lambda_k^-, \lambda_k^+, \lambda) = \sum_{k=1}^N p_k T_k \gamma^{r_k} - \sum_{k=1}^N \lambda_k^- r_k - \sum_{k=1}^N \lambda_k^+ (N - r_k) - \lambda \left(S - \sum_{k=1}^N T_k r_k \right).$$

First-order conditions:

$$\left\{ \begin{array}{l} \frac{\partial L}{\partial r_k} = p_k T_k \log(\gamma) \gamma^{r_k} - \lambda_k^- + \lambda_k^+ + \lambda T_k = 0, \forall k, \\ \lambda_k^- r_k = \lambda_k^+ (N - r_k) = 0, \forall k, \\ \lambda \left(S - \sum_{k=1}^N T_k r_k \right) = 0, \\ \lambda_k^- \geq 0, \quad \lambda_k^+ \geq 0, \forall k, \\ \lambda \geq 0. \end{array} \right.$$

Solution of the relaxed problem

Assuming $\lambda > 0$ is known:

$$r_k = f_k(\lambda) := \max \left(\min \left(\frac{\log(-\lambda/p_k/\log(\gamma))}{\log(\gamma)}, N \right), 0 \right).$$

Plugging this expression in the constraint

$$S = \sum_{k=1}^N T_k r_k$$

we get:

$$S = \sum_{k=1}^N T_k \max \left(\min \left(\frac{\log(-\lambda/p_k/\log(\gamma))}{\log(\gamma)}, N \right), 0 \right),$$

to be solved for λ . The solution exists if

$$S \leq N \sum_{k=1}^N T_k.$$

Practical solution

Define the sets:

$$\mathcal{A}(\lambda) = \{k \text{ such that } \lambda > -p_k \log(\gamma)\}$$

$$\mathcal{B}(\lambda) = \{k \text{ such that } -p_k \log(\gamma) \geq \lambda > -p_k \gamma^N \log(\gamma)\}$$

$$\mathcal{C}(\lambda) = \{k \text{ such that } -p_k \gamma^N \log(\gamma) \geq \lambda \geq 0\} .$$

With these notations, we have

$$f_k(\lambda) = \begin{cases} 0 & \text{if } k \in \mathcal{A}(\lambda), \\ \frac{1}{\log(\gamma)} (\log(\lambda) - \log(-p_k \log(\gamma))) & \text{if } k \in \mathcal{B}(\lambda), \\ N & \text{if } k \in \mathcal{C}(\lambda). \end{cases}$$

and

$$f(\lambda) = N \sum_{k \in \mathcal{C}(\lambda)} T_k + \sum_{k \in \mathcal{B}(\lambda)} \frac{T_k}{\log(\gamma)} (\log(\lambda) - \log(-p_k \log(\gamma)))$$

→ solution of $f(\lambda) = S$ by dichotomy.

The simple “floor” algorithm:

- calculate the solution of the relaxed problem $\{r_1^*, \dots, r_N^*\}$
- for each k , $r_k \leftarrow \lfloor r_k^* \rfloor$

A greedy improvement

- Set $\vec{r}^e = \{r_1, \dots, r_N\}$ given by the “floor” algorithm
- $\mathcal{F} = \{\text{relevant documents}\}$: can increase replication without violating constraints
- while $\mathcal{F} \neq \emptyset$:
 - find $j = \arg \max_j (p_k T_k \gamma^{r_k})$
 - $r_j = r_j + 1$
 - Update \mathcal{F}

Minimizing Variance

Documents have now identical popularity \rightarrow same replication factor k . The question is: how to place them on v hosts? Consider just one document. Such a placement is a **block design** \mathcal{B} of b “blocks”, each being a k -subset of $[1..v]$. Let $\Lambda, \bar{\Lambda}$ the number of (un)available blocks.

Theorem

$$\mathbb{E}(z^{\bar{\Lambda}}) = \sum_{S \subset \mathcal{B}} (z-1)^{|S|} \bar{\delta}^{|\cup_{B \in \mathcal{B}} B|}.$$

The first moments of Λ and $\bar{\Lambda}$ are given by:

$$\begin{aligned}\mathbb{E}(\bar{\Lambda}) &= b \bar{\delta}^k \\ \mathbb{E}(\Lambda) &= b (1 - \bar{\delta}^k) \\ \mathbb{V}(\bar{\Lambda}) = \mathbb{V}(\Lambda) &= \sum_{B, B'} \left(\bar{\delta}^{|\cup B \cup B'|} - \bar{\delta}^{2k} \right).\end{aligned}$$

$$\begin{aligned} \mathbb{V}(\Lambda) &= \sum_{B, B'} \left(\bar{\delta}^{|B \cup B'|} - \bar{\delta}^{2k} \right) \\ &= \sum_{B, B'} \bar{\delta}^{|B|+|B'|-|B \cap B'|} - b(b-1)\bar{\delta}^{2k} \\ &= \sum_{B, B'} \bar{\delta}^{2k} \bar{\delta}^{-|B \cap B'|} - b(b-1)\bar{\delta}^{2k} \end{aligned}$$

MinVar Problem

Let γ be a real number, $\gamma \geq 1$, and b, v, k be integers. The $\text{MinVar}(\gamma, b, v, k)$ problem: find one design \mathcal{B} with $|\mathcal{B}| = b$, $|\mathcal{V}| = v$ and $|B| = k$ for all $B \in \mathcal{B}$, which minimizes the function:

$$J(\mathcal{B}, \gamma) := \sum_{B \neq B' \in \mathcal{B}} \gamma^{|B \cap B'|}.$$

Placement

This algorithm begins with an empty graph and, at each iteration, finds the edge which minimizes $J(\mathcal{B}, \gamma) + J(\mathcal{B}^c, \gamma)$, where \mathcal{B}^c is the complementary design of \mathcal{B} .

- $\mathcal{B} = \emptyset$
- for $\ell \in \{1 \dots k\}$
 - for $i \in \{1 \dots b\}$
 - $j = \arg \min_j \{J(\mathcal{B} \cup (i, j), \gamma) + J((\mathcal{B} \cup (i, j))^c, \gamma)\}$
 - $\mathcal{B} = \mathcal{B} \cup (i, j)$

Random Designs

Random Algorithm

Choose each block uniformly at random over $\binom{[1..v]}{k}$.

Define the function

$$\pi(\gamma) = \binom{v}{k}^{-1} \sum_{j=0}^k \binom{k}{j} \binom{v-k}{k-j} \gamma^j .$$

It is the generating function of $X_{BB'} = |B \cap B'|$, where B and B' are two uniformly chosen random blocks.

Theorem

If \mathcal{B} is a design generated by the Random algorithm, then

$$\mathbb{E}(J(\mathcal{B}, \gamma)) = b(b-1) \pi(\gamma)$$

$$\mathbb{V}(J(\mathcal{B}, \gamma)) = 2b(b-1) (\pi(\gamma^2) - \pi^2(\gamma)) .$$
