

Cheat Sheet

Terminology

Top is the first assumption, y here

Stack alternative name for the list of *Assumptions*

Popping from the stack

Note: in the following example we assume *cmd* does nothing, exactly like `move`, to focus on the effect of the intro pattern.

cmd => x px

Run *cmd*, then pop Top, put it in the context naming it x then pop the new Top and names it px in the context

cmd => [|x xs] //

Run *cmd*, then reason by cases on Top. In the first branch do nothing, in the second one pop two assumptions naming then x and xs. Then get rid of trivial goals. Note that, since only the first branch is trivial, one can write => [|x xs] too. [caveat]: Immediately after `case` and `elim` it does not perform any case analysis, but can still introduce different names in different branches

cmd => /andP[pa pb]

Run *cmd*, then apply the view `andP` to Top, then destruct the conjunction and introduce in the context the two parts naming the pa and pb

cmd => /= {px}

Run *cmd* then simplify the goal then discard px from then context

cmd => [y -> {x}]

Run *cmd* then destruct the existential, then introduce y, then rewrite with Top left to right and discard the equation, then clear x

cmd => /(_ x) h

Introduce h specialized to x

Pushing to the stack

Note: in the following *cmd* is not `apply` or `exact`. Moreover we display the goal just before *cmd* is run.

cmd: (x) y

Push y then push x on the stack. y is also cleared

cmd: {-2}x (erefl x)

Push the type of (erefl x), then push x on the stack binding all but the second occurrence

cmd: _.+1 {px}

Clear px and generalize the goal with respect to the first match of the pattern _.+1

Proof commands

`rewrite` Eab (Exc b).

Rewrite with Eab left to right, then with Exc by instantiating the first argument with b

`rewrite` -Eab {}Eac.

Rewrite with Eab right to left then with Eac left to right, finally clear Eac

`rewrite` /(_ && _).

Unfold the definition of &&

`rewrite` /= -[a]/(0+a) -/c.

Simplify the goal, then change a into 0+a, finally fold back the local definition c

`apply`: H.

Apply H to the current goal

`case`: ab.

Eliminate the conjunction or disjunction

`case`: (leqP a b).

Reason by cases using the leqP spec lemma

`elim`: s.

Perform an induction on s

`elim/last_ind`: s

Start an induction on s using the induction principle last_ind

`have` pa : P a.

Open a new goal for P a. Once resolved introduce a new entry in the context for it named pa

`by` [].

Prove the goal by trivial means, or fail

`exact`: H.

Apply H to the current goal and then assert all remaining goals, if any, are trivial. Equivalent to `by apply`: H.

Reflect and views

`reflect P b`
States that P is logically equivalent to b

`apply: (iffP V)`
Proves a reflection goal, applying the view lemma V to the propositional part of `reflect`. E.g. `apply: (iffP idP)`

```
P : Prop      P : Prop      P : Prop
b : bool      b : bool      b : bool
=====      =====      =====
reflect P b   b -> P       P -> b
```

`apply/V1/V2`
Prove boolean equalities by considering them as logical double implications. The term V1 (resp. V2) is the view lemma applied to the left (resp. right) hand side. E.g. `apply/idP/negP`

```
b1 : bool      b1 : bool      b1 : bool
b2 : bool      b2 : bool      b2 : bool
=====      =====      =====
b1 = ~ b2     b1 -> ~ b2     ~ b2 -> b1
```

`rewrite: (eqP Eab)`
rewrite with the boolean equality Eab

```
Eab : a == b   Eab : a == b
=====      =====
P a           P b
```

Idioms

`case: b => [h1| h2 h3]`
Push b, reason by cases, then pop h1 in the first branch and h2 and h3 in the second

`have /andP[x /eqP->] : P a && b == c`
Open a subgoal for P a && b == c. When proved apply to it the `andP` view, destruct the conjunction, introduce x, apply the view `eqP` to turn b == c into b = c, then rewrite with it and discard the equation

`elim: n.+1 {-2}n (ltnSn n)=> {n} // n`
General induction over n, note that the first goal has a false assumption `forall n, n < 0 -> ...` and is thus solved by //

```
n : nat      n : nat
=====      =====
P n          (forall m, m < n -> P m) ->
             forall m, m < n.+1 -> P m
```

`rewrite lem1 ?lem2 //`
Use the equation with premises `lem1`, then get rid of the side conditions with `lem2`

Searching

`Search _ addn (_ * _) "C" in ssrnat`
Search for all theorems with no constraints on the main conclusion (conclusion head symbol is the wildcard `_`), that talk about the `addn` constant, matching anywhere the pattern `(_ * _)` and having a name containing the string "C" in the module `ssrnat`

Misc notations

```
"f1 \o f2" := (comp f1 f2)
"x \in A" := (in_mem x (mem A))
"x \notin A" := (~ (x \in A))
"[ /\ P1 , P2 & P3 ]" := (and3 P1 P2 P3)
```

```
"[ \/ P1 , P2 | P3 ]" := (or3 P1 P2 P3)
"[ && b1 , b2 , .. , bn & c ]" :=
  (b1 && (b2 && .. (bn && c) .. ))
"[ || b1 , b2 , .. , bn | c ]" :=
  (b1 || (b2 || .. (bn || c) .. ))
"#| A |" := (card (mem A))
"n .-tuple" := (tuple_of n)
"'I_n" := (ordinal n)
"f1 =1 f2" := (eqfun f1 f2)
"b1 (+) b2" := (addb b1 b2)
```

Notations for natural numbers: nat

```
"n .+1" := (succn n)
"n .-1" := (predn n)
"m + n" := (addn m n)
"m - n" := (subn m n)
"m <= n" := (leq m n)
"m < n" := (m.+1 <= n)
"m <= n <= p" := ((m <= n) && (n <= p))
"m * n" := (muln m n)
"n .*2" := (double n)
"m ^ n" := (expn m n)
"n '! " := (factorial n)
"m %/ d" := (divn m d)
"m %% d" := (modn m d)
"m == n %[mod d]" := (m %% d == n %% d)
"m %| d" := (dvdn m d)
"pi .-nat" := (pnat pi)
```

Notations for lists: seq T

```
"x :: s" := (cons _ x s)
"[ :: ]" := nil
"[ :: x1 ]" := (x1 :: [::])
"[ :: x & s ]" := (x :: s)
"[ :: x1 , x2 , .. , xn & s ]" :=
  (x1 :: x2 :: .. (xn :: s) ..)
"[ :: x1 ; x2 ; .. ; xn ]" :=
  (x1 :: x2 :: .. [:: xn] ..)
"s1 ++ s2" := (cat s1 s2)
```

Notations for iterated operations

```
"\big [ op / idx ]_ i F" :=
"\big [ op / idx ]_ ( i | P ) F" :=
"\big [ op / idx ]_ ( i <- r | P ) F" :=
"\big [ op / idx ]_ ( m <= i < n | P ) F" :=
"\big [ op / idx ]_ ( i < n | P ) F" :=
"\big [ op / idx ]_ ( i \in A | P ) F" :=
"\sum_ i F" :=
"\prod_ i F" :=
"\max_ i F" :=
"\bigcap_ i F" :=
"\bigcup_ i F" :=
```

`caveat`: in the general form, the iterated operation `op` is displayed in prefix form (not in infix form) `caveat`: the string "big" occurs in every lemma concerning iterated operations

Rewrite patterns

`rewrite [pat]lem [in pat2]lem2 [X in pat3]lem3`
Rewrite the subterms selected by the pattern `pat` with `lem`. Then in the subterms selected by the pattern `pat2` match the pattern inferred from the left hand side of `lem2` and rewrite the terms selected by it. Last, in the sub terms selected by `pat3` rewrite with `lem3` the sub terms identified by X exactly

`rewrite {3}[in X in pat1]lem1`
Like in `rewrite [X in pat1]lem1` but use the pattern inferred from `lem1` to identify the sub terms of X to be rewritten. Of these terms, rewrite only the third one. Example: `rewrite {3}[in X in f _ X]E`.

```
E : a = c
=====
a + f a (a + a) = f a (a + a) + a
----->
E : a = c
=====
a + f a (a + a) = f a (c + a) + a
```

`rewrite [e in X in pat1]lem1`
Like before, but override the pattern inferred from `lem1` with e

`rewrite [e as X in pat1]lem1`
Like `rewrite [X in pat1]lem1` but match `pat1[X := e]` insted of just `pat1`

`rewrite /def1 -[pat]/term /=`
Unfold all occurrences of `def1`. Then match the goal against `pat` and change all its occurrences into `term` (pure computation). Last simplify the goal

`rewrite 3?lem2 // {hyp} => x px`
Rewrite from 0 to 3 times with `lem2`, then try to solve with `by []` all the goals. Finally clear `hyp` and introduce x and px

Pattern matching detailed rules

`pattern` a term, possibly containing `_`

`key` The head symbol of a pattern

The sub terms selected by a pattern:

- the goal is traversed outside in, left to right, looking for verbatim occurrences of the key
- the sub terms whose key matches verbatim are higher order matched (i.e. up to definition unfolding and recursive function computation) against the pattern
- if the matching fails, the next sub term whose key matches is tried
- if the matching succeeds, the sub term is considered to be the (only) instance of the pattern
- the sub terms selected by the pattern are then all the copies of the instance of the pattern
- these copies are searched looking again at the key, and higher order comparing the arguments pairwise

Note: occurrence numbers can be combined with patterns. They refer to the list of sub terms selected by the (last) pattern (i.e. they are processed at the very end).

`set n := {2 4}(_ + b)`
Put in the context a local definition named n for the second and fourth occurrences of the sub terms selected by the pattern `(_ + b)`

```
=====
a + c + (a + b) + (a + b) =
a + (a + b) + (0 + a + b) + c
----->
n := a + b
=====
a + c + (a + b) + n =
a + (a + b) + n + c
```
