

## From EULER Project

# PmWiki: Passwords

PmWiki has built-in support for password-protecting various areas of the wiki site. Authors generally want to be able to apply passwords to individual pages or to wiki groups. Wiki Administrators can apply passwords to individual pages, to wiki groups, or to the entire site. As with any access control system, the password protection mechanisms described here are only a small part of overall system and wiki security.

## As an author editing pages...

An author will generally set 3 types of passwords:

1. to control who can see a page or group, use `read` passwords
2. to control who can edit a page or group, use `edit` passwords
3. to control who can alter the passwords used to protect a page or group, use `attr` passwords

*To set a password on an individual wiki page, add*

`?action=attr`

to the page's URL (address) to access its attributes. Using the form on the attributes page, you can set or clear the `read`, `edit`, or `attr` passwords on the page. In the form you enter the passwords as cleartext; PmWiki encrypts them for you automatically when it stores them.

Additional options:

- Leaving a field blank will leave the attribute unchanged.
- To remove a password from a page (*reverting back* to the group's or site's default), enter

clear

- To indicate that the page can be edited *even if a group or site password is set*, enter

@nopass

- To lock a page for everybody but the admin, enter

@lock

- To assign the site's site-wide edit-password to the `read`, `edit`, or `attr` password for the page, enter

@\_site\_edit

*To set a password on a wiki group* is slightly more difficult -- you just set the passwords on a special page in each group called

GroupAttributes

First, you can get to the attributes page for GroupAttributes by entering a URL (address) like

`http://www.example.com/pmwiki/pmwiki.php?n=GroupName.GroupAttributes?action=att`

Replace `www.example.com` with your domain name, and `GroupName` with the name of the group

Then, using the form on the attributes page, you can set or clear the `read`, `edit`, or `attr` passwords for the entire group. In the form you enter the passwords as cleartext; PmWiki encrypts them for you automatically.

Additional options:

- To remove a password from a group (*reverting back* to the site's default), enter

`clear`

- To indicate that the group can be edited *even if a site password is set*, enter

`@nopass`

- To lock a group for everybody but the admin, enter

`@lock`

**Multiple passwords for a page, group or site** are allowed. Simply enter multiple passwords separated by a space. This allows you to have a read password, a write password, and have the write password allow read/write access. In other words, if the read password is

`alpha`

and the edit password is

`beta`

then enter

```
Set new read password: alpha beta
```

```
Set new edit password: beta
```

This says that either

`alpha`

or

`beta`

can be used to read pages, but only

`beta`

may edit. Since PmWiki checks the passwords you've entered since the browser has been opened, entering a read password that is also a write password allows both reading and writing.

administrator

## As an administrator ...

You can set passwords on pages and groups exactly as described above for authors. You can also:

1. set site-wide passwords for pages and groups that do not have passwords
2. use `attr` passwords to control who is able to set passwords on pages

As an author editing pages...

3. use `upload` passwords to control access to the file `upload` capabilities (if uploads are enabled)
4. use an `admin` password to override the passwords set for any individual page or group

For more information on password options available to administrators, see [PasswordsAdmin](#).

## Which password wins?

In PmWiki, page passwords override group passwords, group passwords override the *default* passwords, and the `admin` password overrides all passwords. This gives a great deal of flexibility in controlling access to wiki pages in PmWiki.

## Opening access to pages in protected groups/sites

Sometimes we want to "unprotect" pages in a group or site that is otherwise protected. In these cases, the special password

`@nopass`

is used to indicate that access should be allowed to a page without requiring a password.

For example, suppose `Main.GroupAttributes` has an edit password set, thus restricting the editing of all pages in `Main`. Now we want `Main.WikiSandbox` to be editable without a password. Using

`clear`

for the edit password for `Main.WikiSandbox` *doesn't unprotect the page*, because the password is being set by the group. Instead, we set the edit password for `Main.WikiSandbox` to the special value

`@nopass`

which tells PmWiki to ignore any site-wide or group-level passwords for that page.

How can I password protect all the pages and groups on my site? Do I really have to set passwords page by page, or group by group?

Administrators can set passwords for the entire site by editing the `config.php` file; they don't have to set passwords for each page or group. For example, to set the entire site to be editable only by those who know an "edit" password, an administrator can add a line like the following to `local/config.php`:

```
$DefaultPasswords['edit'] = crypt('edit_password');
```

For more information about the password options that are available only to administrators, see [PasswordsAdmin](#).

I get http error 500 "Internal Server Error" when I try to log in. What's wrong?

This can happen if the encrypted passwords are not created on the web server that hosts the PmWiki.

The `crypt` function changed during the PHP development, e.g. a password encrypted with PHP 5.2 can not be decrypted in PHP 5.1, but PHP 5.2 can decrypt passwords created by PHP 5.1.

This situation normally happens if you prepare everything on your local machine with the latest PHP version and you upload the passwords to a webserver which is running an older version.

The same error occurs when you add encrypted passwords to `local/config.php`.

Solution: Create the passwords on the system with the oldest PHP version and use them on all other systems.

How can I create private groups for users, so that each user can edit pages in their group, but no one else (other than the admin) can?

Administrators can use the [AuthUser](#) recipe and add the following few lines to their local/config.php file to set this up:

```
$group = FmtPageName('$Group', $pagename);  
$DefaultPasswords['edit'] = 'id:'.$group;  
include_once("$FarmD/scripts/authuser.php");
```

This automatically gives edit rights to a group to every user who has the same user name as the group name.

How come when I switch to another wiki within a farm, I keep my same authorization?

PmWiki uses PHP sessions to keep track of authentication/authorization information, and by default PHP sets things up such that all interactions with the same server are considered part of the same session.

An easy way to fix this is to make sure each wiki is using a different cookie name for its session identifier. Near the top of one of the wiki's local/config.php files, before calling authuser or any other recipes, add a line like:

```
session_name('XYZSESSID');
```

You can pick any alphanumeric name for XYZSESSID; for example, for the cs559-1 wiki you might choose

```
session_name('CS559SESSID');
```

This will keep the two wikis' sessions independent of each other.
