PmWiki: Requirements

Prerequisites for running the PmWiki wiki engine:

1. <u>PHP</u> 4.1 or later
     - ♦ PHP 5<u>(approve sites)</u> or later is recommended
2. Some sort of webserver that can run PHP scripts.

PmWiki has been reported to work with the following OS/webserver combinations:

- Apache 1.3 or 2.0, on roughly anything (Unix, Linux, Windows, and Mac OS/X)
    - ♦ Apache 2.2<u>(approve sites)</u> or later is recommended
- Microsoft Internet Information Server, on Windows
- I got it to work on appWeb (a very small, php-enabled webserver) executing on a Linksys NSLU2 Network Storage Link device (runs Unslung 5.5 beta which is a Linux derivate for embedded systems). Still have to work out why file-uploads does not seem to work, however. --Hans-Göran Puke
- PmWiki works very well on x86 Linux + LiteSpeedWeb Server<u>(approve sites)</u> Standard Edition --Jeff Muday

PmWiki has been reported not to work on:

- Mac OS before Mac OS X because there's no PHP available

The <u>Standalone</u> recipe provides a special, bare-bones webserver application that can be used to run PmWiki in places where another webserver isn't available. PmWIki can also be run from a <u>USB drive</u>.
