

M2 Internship Proposal: Reasoning over Bounded First-Order Logic Ontologies

David Carral

LIRMM, Inria, University of Montpellier, CNRS, France
david.carral@inria.fr

1 Introduction

Hi! I'm reaching out to recruit a student to collaborate with me for a few months next year. Before diving into the technical details of this proposal (see Section 2), I'd like to introduce myself and discuss some details about our potential collaboration.

My research topics. Broadly speaking, I am interested in the study of logical languages (mostly first-order logic, Description Logics, and existential rules), their theoretical/computational properties, and the implementation of reasoning algorithms for these languages. To know a bit more about my work, you can check out my webpage, DBLP profile, or Google Scholar :

- Personal page: <https://www-sop.inria.fr/members/David.Carral/>
- DBLP: <https://dblp.org/pid/00/11425.html>
- Google: <https://scholar.google.com/citations?user=5bEOMysAAAAJ>

Brief academic history.

- From 9/12 to 10/16: Ph.D. in Computer Science and Engineering at Wright State University.
- From 11/16 to 12/20: Postdoctoral Researcher at Technische Universität Dresden
- From 1/21 onwards: CRCN Researcher at Inria

What I am looking for. I am looking for a student who is intrinsically motivated to pursue a research topic of mutual interest. I propose one such topic in this document but if you want to work on something else, reach out to me to discuss about it. Alternatively, I have listed some really interesting open problems in my webpage! I would be happy to discuss those as well.

What I offer. Long story short, I offer close and active supervision to help you solve some interesting research question. On top of that, I am pretty sure that I can also provide funding for up to 6 months but we are going to have to double check this.

Prerequisite knowledge. I assume that you are somewhat familiar with the syntax and semantics of first-order logic (FOL) as well as with basic notions from computational and complexity theory. On top of that, it would be great if you knew a bit about logical languages such as Description Logics, datalog, or existential rules but this is not a necessary requirement.

Contact me! I am writing this document in a bit of a haste and hence, it is probably not as clear as I would like it to be. To make up for this, I encourage you to contact me if you have questions; we can schedule an online meeting to discuss any details (technical or otherwise) regarding this proposal.

2 The Research Plan

2.1 Preliminaries

Let me first present some preliminary notions necessary to introduce our research question later on:

- For a first-order formula β and a list \vec{x} of variables, we write $\beta[\vec{x}]$ to indicate that \vec{x} is the set of all free variables that occur in β . Note that we often identify a list of variables with the corresponding set.
- An (*disjunctive existential*) *rule* is a first-order formula of the form

$$\forall \vec{x}. (\beta[\vec{x}] \rightarrow \bigvee_{i=1}^n \exists \vec{y}_i. \eta[\vec{x}_i, \vec{y}_i]) \quad (1)$$

where \vec{x} , \vec{z} , \vec{y}_1, \dots , and \vec{y}_n are pairwise disjoint lists of variables; all variables in \vec{x}_i occur in \vec{x} for every $1 \leq i \leq n$; and β, η_1, \dots , and η_n are non-empty conjunctions of atoms. Such a rule is *deterministic* if $n = 1$; that is, if it is disjunction-free. Often, we ignore universal quantifiers when writing rules.

- In the context of this proposal, an *ontology* is set of rules. A *deterministic ontology* is a set of deterministic rules.
- A *fact* is an atomic first-order formula $P(c_1, \dots, c_n)$ where P is an n -ary predicates and all c_1, \dots, c_n are constants.
- A (*Boolean conjunctive*) *query* is a first-order formula of the form $\exists \vec{y}. \beta[\vec{y}]$ with β a conjunction of atoms. That is, a query is an existentially closed conjunction of atoms.
- A *homomorphism* is a partial function h that maps variables to terms.
 - For a term t ; we define $t^h = h(t)$ if t is in the domain of h , and $t^h = t$ otherwise.
 - For an atom $P(t_1, \dots, t_n)$, let $h(P(t_1, \dots, t_n)) = P(t_1^h, \dots, t_n^h)$.
 - For some sets \mathcal{A} and \mathcal{B} of atoms; we write $h : \mathcal{A} \rightarrow \mathcal{B}$ to indicate that the domain of h is the set of all variables in \mathcal{A} , and that $h(\alpha) \in \mathcal{B}$ for every $\alpha \in \mathcal{A}$.

2.2 The Problem of Ontology Based Entailment (OBE)

Here's an interesting problem, which I often consider in my own research:

ONTOLOGY BASED QUERY ENTAILMENT (OBQE)

- **Input:** an ontology \mathcal{R} , a fact set \mathcal{F} , and a query v
 - **Output:** yes iff the $\mathcal{R} \cup \mathcal{F} \models v$; that is, if $\mathcal{R} \cup \mathcal{F}$ entails v under standard first-order semantics.

It is out of the scope of this document to motivate this problem or to elaborate why it is relevant, both in theory and in practice. If you would

like to learn more about it, I recommend a lecture¹ by Professor Sebastian Rudolph at the TU Dresden.

Since the OBQE problem is undecidable [2], intense research efforts have been aimed at finding expressive properties of ontologies that guarantee that it can be solved in many real-world cases. A powerful approach to retrieve decidability of OBQE is based on query rewriting techniques. The idea is to rewrite the query with respect to the ontology, and then check if the resulting rewriting is evaluated directly over the input fact set.

Definition 2.1 Consider an ontology \mathcal{R} and a query v .

- A rewriting for the pair $\langle \mathcal{R}, v \rangle$ is a finite set \mathcal{Q} of queries such that, for every fact set \mathcal{F} , we have that $\mathcal{R} \cup \mathcal{F} \models v$ iff $\mathcal{F} \models \gamma$ for some $v \in \mathcal{Q}$.
- The tuple $\langle \mathcal{R}, v \rangle$ is rewritable if it admits a rewriting.
- The ontology \mathcal{R} is rewritable if $\langle \mathcal{R}, \gamma \rangle$ is rewritable for every query γ .

Intuitively, a rewriting compiles the information in the input rule set and the query into a finite set of queries. Afterwards, we can directly check entailment by directly checking entailment against a set of facts. Let's have a look at a couple of examples to better understand this notion.

Example 2.1 Consider the (rather simple) ontology \mathcal{R} and the query v :

$$\mathcal{R} = \{ \text{Person}(x) \rightarrow \text{Mortal}(x) \} \quad v = \exists y. \text{Mortal}(y)$$

Intuitively, the query v asks if there are any “mortals” and the only rule in \mathcal{R} states that every “person” is a “mortal”. Hence, if there is some “person” in a given fact set, then the query v is entailed with respect to the given rule set. Then, the query set $\mathcal{Q} = \{ \exists x. \text{Mortal}(x), \exists x. \text{Person}(x) \}$ is a rewriting for $\langle \mathcal{R}, v \rangle$. That is, for any given fact set \mathcal{F} , we have that:

$$\mathcal{R} \cup \mathcal{F} \models \exists y. \text{Mortal}(y) \iff (\mathcal{F} \models \exists x. \text{Mortal}(x) \text{ or } \mathcal{F} \models \exists x. \text{Person}(x))$$

Example 2.2 The pair $\langle \{ \text{Path}(x, y) \wedge \text{Path}(y, z) \rightarrow \text{Path}(x, z) \}, \text{Path}(s, t) \rangle$, where s and t are some constants, is not rewritable. Note that rewritings are finite sets by definition, and that any valid rewriting this pair would have to, for every $n \geq 1$, contain the following query:

$$\exists \vec{w}. \text{Path}(s, w_0) \wedge \text{Path}(w_0, w_1) \wedge \text{Path}(w_1, w_2) \wedge \dots \wedge \text{Path}(w_n, t)$$

¹Introduction to Existential Rules: [https://iccl.inf.tu-dresden.de/web/Introduction_to_Existential_Rules_\(SS2024\)/en](https://iccl.inf.tu-dresden.de/web/Introduction_to_Existential_Rules_(SS2024)/en)

Given some input ontology \mathcal{R} , a fact set \mathcal{F} , and a query v , we can solve the OBQE problem if \mathcal{R} is rewritable. That is, we can effectively verify that $\mathcal{R} \cup \mathcal{F} \models v$. If \mathcal{R} is indeed rewritable, decidability is achieved by first using a (terminating) algorithm to compute a rewriting \mathcal{Q} for $\langle \mathcal{R}, v \rangle$ [4, 5], and then simply checking if $\mathcal{F} \models \exists \vec{y}. \beta$ for some $\exists \vec{y}. \beta \in \mathcal{Q}$;² this algorithm is sound and complete by Definition 2.3. Indeed, rewritability is the basis for many well-known ontological languages such as DL-Lite [1] or sticky rules [3].

Rewritability also guarantees decidability in the presence of disjunctions. However, this property is not very expressive in the non-deterministic setting; that is, there are barely any ontologies with disjunctions that are actually rewritable. For instance, see the following example showcasing a singleton ontology that is not rewritable:

Example 2.3 Consider the (extremely simple) ontology \mathcal{R} and the query v :

$$\begin{aligned} \mathcal{R} &= \{ \text{Edge}(x, y) \rightarrow \text{Source}(x) \vee \text{Target}(y) \} \\ v &= \exists x, y. \text{Source}(x) \wedge \text{Edge}(x, y) \wedge \text{Target}(y) \end{aligned}$$

In this case, the tuple $\langle \mathcal{R}, v \rangle$ is not rewritable since any valid rewriting for this pair would have to, for every $n \geq 0$, contain the following query:

$$\exists \vec{x}. \text{Source}(x_0) \wedge \text{Edge}(x_0, x_1) \wedge \text{Edge}(x_1, x_2) \wedge \dots \wedge \text{Target}(x_n)$$

Summing things up, even though rewritability does guarantee decidability in the presence of disjunctions, this property is not very useful in practice because it is not very general. Hence, we are going to consider an alternative definition of this property.

Boundedness. If we are only interested in deterministic ontologies, we can achieve an equivalent definition for rewritability by checking if an ontology is recursive. Intuitively, you can realise that the ontology from Example 2.2 is recursive, since the rule in the ontology may produce facts over the predicate *Path* that need to be considered when deriving further consequences. In contrast, the ontology from Example 2.3 is clearly not recursive; that is, this ontology is *bounded*. Let's give a formal definition of boundedness via the chase algorithm, which is a bottom-up materialisation procedure that produces all of the consequences for a deterministic input ontology.

²We have that $\mathcal{F} \models \exists \vec{y}. \beta$ if and only if there is a homomorphism $h : \beta \rightarrow \mathcal{F}$. Note that here we identify β , which is a conjunction, with the corresponding set of facts.

Definition 2.2 Consider the following:

- For an atom set \mathcal{A} , a deterministic rule $\rho = \beta \rightarrow \exists \vec{y}.\eta$, and a homomorphism $h : \beta \rightarrow \mathcal{A}$,³ let $\text{Output}(\mathcal{A}, \rho, h) = h'(\eta)$ where h' is the extension of h that maps every variable $y \in \vec{y}$ to a fresh term t_y^h unique for y and h .
- For an atom set \mathcal{A} and a deterministic rule $\rho = \beta \rightarrow \exists \vec{y}.\eta$, let $\text{Output}(\mathcal{A}, \rho)$ be the set atom that includes the set $\text{Output}(\mathcal{A}, \rho, h)$ for every homomorphism $h : \beta \rightarrow \mathcal{A}$.
- For a deterministic ontology \mathcal{R} and an atom set \mathcal{A} , let $\mathcal{R}(\mathcal{A})$ be the atom set $\mathcal{A} \cup \bigcup_{\rho \in \mathcal{R}} \text{Output}(\mathcal{A}, \rho)$.
- For a deterministic ontology \mathcal{R} and an atom set \mathcal{A} ; we define $\text{Chase}_0(\mathcal{R}, \mathcal{A}) = \mathcal{A}$, and $\text{Chase}_i(\mathcal{R}, \mathcal{A}) = \mathcal{R}(\text{Chase}_{i-1}(\mathcal{R}, \mathcal{A}))$ for every $i \geq 1$. Moreover, let $\text{Chase}_\infty(\mathcal{R}, \mathcal{A}) = \bigcup_{i=0}^n \text{Chase}_i(\mathcal{R}, \mathcal{A})$.

Consider an input ontology \mathcal{R} and a fact set \mathcal{F} . Then, at each step of the chase (i.e., at each $\text{Chase}_i(\mathcal{R}, \mathcal{F})$) we may derive more and more consequences. If we could go all the way, then we could guarantee soundness and completeness of query entailment:

Theorem 2.1 For an ontology \mathcal{R} , a fact set \mathcal{F} , and a query v ; we have that $\mathcal{R} \cup \mathcal{F} \models v$ if and only if $\text{Chase}_\infty(\mathcal{R}, \mathcal{F}) \models v$.

Now, using the chase as our recursive algorithm for query entailment, we are finally ready to define boundedness.

Definition 2.3 Consider a deterministic ontology \mathcal{R} and a query v .

- The tuple $\langle \mathcal{R}, v \rangle$ is bounded if, for every fact set \mathcal{F} , there is some $k \geq 1$ such that $\mathcal{R} \cup \mathcal{F} \models v$ iff $\text{Chase}_k(\mathcal{R}, \mathcal{F}) \models v$.
- The ontology \mathcal{R} is bounded if $\langle \mathcal{R}, \gamma \rangle$ is bounded for every query γ .

Intuitively, the tuple $\langle \mathcal{R}, v \rangle$ above is bounded if we can check entailment against the k -th step of the chase for some fixed $k \geq 0$, which must be independent on the fact set \mathcal{F} . If this is the case, the chase is not a really recursive algorithm anymore since we only need to compute the chase step operation a fixed number of times.

³Here again we identify the conjunction β of atoms with the corresponding set.

Exercise 2.1 *Informally argue that the ontologies in Example 2.1 and 2.2 are and are not bounded, respectively.*

As previously mentioned, boundedness and rewritability do coincide for deterministic ontologies.

Theorem 2.2 *For a deterministic ontology \mathcal{R} and a query v , the tuple $\langle \mathcal{R}, v \rangle$ is rewritable iff $\langle \mathcal{R}, v \rangle$ is bounded. Moreover, the ontology \mathcal{R} is rewritable iff \mathcal{R} is bounded.*

Exercise 2.2 (A bit hard!) *Argue the “only if” direction of the first sentence in Theorem 2.2.*

Our research goal. In the presence of disjunctions, the definitions of rewritability and boundedness do not coincide anymore.⁴ In fact the latter property does imply the former but the converse implication does not hold; for example, the ontology in Example 2.3 is bounded but not rewritable. So, in the non-deterministic setting, boundedness is more general than rewritability and hence this property could be way more useful in practice. But (here’s the catch), does boundedness guarantee decidability of the OBQE problem in the presence of disjunctions? Indeed, this is the question that we would like to solve during your internship!

3 Contact Me!

Looking back, I can see that this proposal is perhaps a bit too technical. Unfortunately, I do not have the time to write something clearer and more intuitive. Moreover, there are probably typos here and there... To make up for this, I would like to encourage you to contact me if you have any questions about this document (my email is under my name in the first page of this document) and let’s just set up a online meeting.

Also, please do not feel intimidated by the task that I have proposed. If you find it interesting, please contact me even if you have no idea how to solve it. We can discuss some strategies and see if something works out.

⁴I would be happy to provide you with a formal definition of boundedness for disjunctive ontologies in an online meeting; I have written enough technical stuff for the day.
