Abstract

Existential rules are a very popular ontology-mediated query language for which the chase represents a generic computational approach for query answering. It is straightforward that existential rule queries exhibiting chase termination are decidable and can only recognize properties that are preserved under homomorphisms. In this paper, we show the converse: every decidable query that is closed under homomorphism can be expressed by an existential rule set for which the standard chase universally terminates. Membership in this fragment is not decidable, but we show via a diagonalisation argument that this is unavoidable.

1 Introduction

At the core of contemporary logic-based knowledge representation is the concept of querying data sources, often using elaborate query formalisms that allow for taking background knowledge into account. The classical decision problem related to such knowledge-aware querying is Boolean query entailment. From an abstract point of view, a Boolean query identifies a class of databases $D$ – those that satisfy the query, i.e., to which the query “matches”. This view allows us to define and investigate properties of (abstract) queries independently from the syntax used to specify them. Such properties can be structural (morphisms, closure properties) or computational (decidability, complexity).

A very popular querying formalism are existential rules, also referred to as tuple-generating dependencies. It is straightforward that the class of databases satisfying some existential rule query is closed under homomorphisms and recursively enumerable. Conversely, it was established that every homomorphism-closed query that is recursively enumerable can be expressed using existential rules (Rudolph and Thomazo 2015). That is, plain existential rules already realize their full potential: further syntactic extensions within these boundaries do not enhance expressivity.

For questions related to automated deduction, however, a more restricted requirement than recursive enumerability is of central interest: decidability. Therefore, the crucial question we tackle in this paper is:

Can we characterize an existential rules fragment capable of expressing every decidable homomorphism-closed query?

The generic computational paradigm for existential rules, the chase (Beeri and Vardi 1984), is based on repetitive, forward-chaining rule application, starting from the database. As this may cause the iterated introduction of new domain elements, this procedure is not guaranteed to terminate – yet, termination is a crucial criterion for decidability. The chase comes in several variants, mainly differing in their increasingly thorough mechanisms to prevent unnecessary rule applications: While the Skolem chase (Marnette 2009) essentially just avoids duplicate rule applications, the standard (Fagin et al. 2005) and the core chase (Deutsch, Nash, and Remmel 2008) check for redundancy on a local and global level, respectively.

The class of existential rule sets with terminating$^1$ Skolem chase has already been weighed and found wanting: it only comprises those queries that are already expressible in plain Datalog – and hence can be evaluated in polynomial time (Marnette 2009; Krötzsch and Rudolph 2011; Zhang, Zhang, and You 2015). For the standard-chase-terminating and the core-chase-terminating existential rules classes, on the other hand, we only know that the former is contained in the latter (Grahne and Onet 2018), but little more than that (Krötzsch, Marx, and Rudolph 2019). In this paper, we clarify the situation significantly by showing the following:

Standard-chase-terminating existential rules capture the class of all decidable homomorphism-closed queries.

Notably, this implies that standard-chase-terminating and core-chase-terminating existential rule queries are equally expressive and no decidable enhancement of this formalism that preserves homomorphism-closedness (e.g. by allowing disjunction in rule heads) can be strictly more expressive.

As a downside, the existential rules fragment thus identified is not even semi-decidable, but we show via a diagonalisation argument that this downside is, in fact, unavoidable.

Additional proofs and details are given in the appendix.

2 Preliminaries

Rules We consider first-order formulas over countably infinite sets $\text{Vars}$ of variables and $\text{Preds}$ of predicates, where each $p \in \text{Preds}$ has an arity $\mathsf{Ar}(p) \geq 0$. Lists of variables are denoted $\bar{x} = x_1, \ldots, x_k$ and will be treated like sets when order is not relevant. An atom is an expression $p(\bar{x})$ with $p \in \text{Preds}$ and $|\bar{x}| = \mathsf{Ar}(p)$.

$^1$We always mean universal termination, i.e., for every database.
The fragment of disjunctive existential rules consists of formulæ of the form:

$$\forall \bar{x}. \left( \beta[\bar{x}] \rightarrow \bigvee_{i=1}^{k} \exists \bar{y}_i \cdot \eta_i[\bar{x}, \bar{y}_i] \right),$$

(1)

where $\beta[\bar{x}]$ and $\eta_i[\bar{x}, \bar{y}_i]$ ($i = 1, \ldots, k$) are conjunctions of atoms with variables $\bar{x}$ and $\bar{y}_i$, respectively. We call $\beta$ body and $\bigvee_{i=1}^{k} \exists \bar{y}_i \cdot \eta_i$ head. Bodies can be empty (we then omit $\rightarrow$), but heads must be non-empty. We require that $\bar{x}$ and $\bar{y}_i$ ($i = 1, \ldots, k$) are mutually disjoint and that $\bar{x} \subseteq \bar{x}_i$ for all $i = 1, \ldots, k$. We single out the fragment of existential rules by disallowing disjunction, i.e. requiring $k = 1$, and Datalog rules by disallowing existential quantifiers. We often omit the universal quantifiers from rules and treat conjunctions of atoms as sets of atoms.

### Databases, Interpretations, and Entailment

The semantics of formulæ is based on logical interpretations, which we define as relational structures over a countably infinite set $\text{Nulls}$ of nulls. A schema $\mathcal{S}$ is a finite set of predicates. An interpretation $\mathcal{I}$ over schema $\mathcal{S}$ is a set of expressions $p(\bar{\eta})$ with $p \in \mathcal{S}$ and $\bar{\eta}$ a list of nulls of length $\text{Ar}(p)$. We write $\text{Nulls}(\mathcal{I})$ for the set of nulls in $\mathcal{I}$. A database is a finite interpretation. See also the remarks on this notation below.

A homomorphism $h : \mathcal{I}_1 \rightarrow \mathcal{I}_2$ between interpretations $\mathcal{I}_1$ and $\mathcal{I}_2$ is a mapping $h$ from the nulls in $\mathcal{I}_1$ to the nulls in $\mathcal{I}_2$, such that $p(\bar{\eta}) \in \mathcal{I}_1$ implies $p(h(\bar{\eta})) \in \mathcal{I}_2$, where $h(\bar{\eta})$ denotes the list of $h$-values over $\bar{\eta}$. We also write $h(\mathcal{I})$ for $(p(h(\bar{\eta}))) \cup \{p(\bar{\eta}) \mid p(\bar{\eta}) \in \mathcal{I}\}$.

A substitution $\sigma$ is a mapping from variables to nulls, which we extend to lists of variables and formulæ as usual. A rule $\rho$ as in (1) is satisfied by interpretation $\mathcal{I}$ if every substitution $\sigma : \bar{x} \rightarrow \text{Nulls}$ with $\sigma(\beta) \subseteq \mathcal{I}$ can be extended to a substitution $\sigma' : \bar{x} \cup \bar{y}_i \rightarrow \text{Nulls}$ for some $i \in \{1, \ldots, k\}$ such that $\sigma'(\eta_i) \subseteq \mathcal{I}$. Otherwise, if $\sigma(\beta) \subseteq \mathcal{I}$ but no extension $\sigma'$ of $\sigma$ verifies $\sigma'(\eta_i) \subseteq \mathcal{I}$ for some $i \in \{1, \ldots, k\}$, then $(\rho, \sigma)$ is applicable to $\mathcal{I}$.

$\mathcal{I}$ satisfies a set $\Sigma$ of rules if it satisfies every rule in $\Sigma$. An interpretation $\mathcal{J}$ is satisfied by an interpretation $\mathcal{I}$ if there is a homomorphism $h : \mathcal{J} \rightarrow \mathcal{I}$. $\mathcal{I}$ is a model of a rule/rule set/interpretation/database $\mathcal{X}$ if $\mathcal{X}$ is satisfied by $\mathcal{I}$, written $\mathcal{I} \models \mathcal{X}$. As usual, we also write $\mathcal{X} \models \mathcal{Y}$ ("$\mathcal{X}$ entails $\mathcal{Y}$") if every model of $\mathcal{X}$ is a model of $\mathcal{Y}$, where $\mathcal{X}$ and $\mathcal{Y}$ might be rules, rule sets, databases, or lists of several such elements. Note that the semantics of a database $\mathcal{D}$ in this context corresponds to the semantics of a Boolean conjunctive query $\exists \bar{x}. \bigwedge \{p(x_{n_1}, \ldots, x_{n_\ell}) \mid p(n_1, \ldots, n_\ell) \in \mathcal{D}\}$ – we will therefore not introduce such queries as a separate notion. Also note that entailment and satisfaction between interpretations/databases coincide.

### Abstract Queries, Expressivity, and Decidability

An (abstract) query $\Omega$ over a schema $\mathcal{S}$ is a set of databases over $\mathcal{S}$ that is closed under isomorphism, i.e., such that whenever $\mathcal{D} \in \Omega$ and $\mathcal{D}'$ is obtained from $\mathcal{D}$ by bijective renaming of nulls, then $\mathcal{D}' \in \Omega$. $\Omega$ is further closed under homomorphisms if, for all $\mathcal{D} \in \Omega$ and homomorphisms $h : \mathcal{D} \rightarrow \mathcal{D}'$, we have $\mathcal{D}' \in \Omega$.

**Definition 1.** Let $\text{Goal}$ be a nullary predicate. A query $\Omega$ over $\mathcal{S}$ is expressed by a set $\Sigma$ of rules if, for every database $\mathcal{D}$ over $\mathcal{S}$, we have $\mathcal{D} \in \Omega$ if and only if $\Sigma, \mathcal{D} \models \text{Goal}$.

To discuss decidability of queries, we need to conceive databases as Turing machines inputs over a fixed alphabet. A serialization for a schema $\mathcal{S}$ is a word $s \in \{(0, 1, \|, \+) \cup \mathcal{S}\}^*$ of the form $e_1 \cdots e_n$ where $n \geq 0$ and $e_i = p_1\|w_{i1}) \cdots \|w_{ik}(p_i)\|$ for $w_{ij} \in \{0, 1\}^+$ and $p_i \in \mathcal{S}$.

Given $s$ of this form and an injection $\eta : \{0, 1\}^+ \rightarrow \text{Nulls}$, let $\eta(s)$ denote the database $\{p_i(\eta(w_{i1}), \ldots, \eta(w_{ik}(p_i))) \mid 1 \leq i \leq n\}$. Then $s$ corresponds to a database $\mathcal{D}$ if $\eta(s)$ is isomorphic to $\mathcal{D}$; note that this does not depend on the choice of $\eta$.

A query $\Omega$ with schema $\mathcal{S}$ is decidable if the set of all serializations for $\mathcal{S}$ that correspond to some $\mathcal{D} \in \Omega$ is a decidable language.

### Remarks on our Notation

Many works consider constants to appear in databases (not just nulls), but complexity and expressivity is usually studied for queries that are closed under isomorphisms, a.k.a. generic (Abiteboul, Hull, and Vianu 1995, Ch. 16), and nulls are more natural there. One can admit finitely many exceptions (elements that must not be renamed), but such “constants” can be simulated by marking them with dedicated unary predicates.

Specifying logical interpretations as sets of “atoms” that may use nulls is a notational convenience with some side effects: our interpretations cannot contain elements that do not stand in any relation, but they can have an empty domain. Both aspects do not change the notion of logical entailment on the formulas we consider.

### Universal Models and the Chase

Entailment of databases (corresponding to Boolean conjunctive queries) can be decided by considering only a subset of all models. Given sets $\mathcal{I}$ and $\mathcal{R}$ of interpretations, $\mathcal{I}$ is universal for $\mathcal{R}$ if, for all $\mathcal{K} \in \mathcal{R}$, there is $\mathcal{I} \in \mathcal{I}$ and a homomorphism $\mathcal{I} \rightarrow \mathcal{K}$.

Consider a rule set $\Sigma$ and database $\mathcal{D}$, and let $\mathcal{M}$ be the set of all models of $\Sigma$, $\mathcal{D}$. Then $\mathcal{I}$ is a universal model set for $\Sigma$ and $\mathcal{D}$ if $\mathcal{I} \in \mathcal{M}$ and $\mathcal{I}$ is universal for $\mathcal{M}$.

**Fact 1.** If $\mathcal{I}$ is a universal model set for $\Sigma$ and $\mathcal{D}$ then, for every database $\mathcal{C}$, we have $\Sigma, \mathcal{D} \models \mathcal{C}$ if and only if $\mathcal{I} \models \mathcal{C}$ for all $\mathcal{I} \in \mathcal{I}$.

Universal model sets can be computed with the chase algorithm. Here, we consider a variation of the standard (or restricted) chase for rules with disjunction, introduced by (Carral, Dragoste, and Krötzsch 2017).

**Definition 2.** A chase tree for a rule set $\Sigma$ and database $\mathcal{D}$ is a (finite or infinite) tree where each node is labelled by a database, such that:

1. The root is labelled with $\mathcal{D}$.
2. For every node with label $\mathcal{E}$ that has $\ell$ children labelled $\mathcal{C}_1, \ldots, \mathcal{C}_\ell$, there is a rule $\rho \in \Sigma$ of the form (1) and a substitution $\sigma : \bar{x} \rightarrow \text{Nulls}$ such that (i) $(\rho, \sigma)$ is applicable to $\mathcal{E}$, (ii) $\rho$ has $k = \ell$ head disjuncts, and (iii) $\mathcal{C}_i = \mathcal{E} \cup \sigma_i(\eta_i)$ where $\sigma_i$ extends $\sigma$ by mapping each variable $y_i \in \bar{y}_i$ to a fresh null.

3. For each rule $\rho \in \Sigma$ and each substitution $\sigma$, there is $i \geq 1$ such that $\langle \rho, \sigma \rangle$ is not applicable to the label of any node of depth $\geq i$.

The result that corresponds to a chase tree is the set of all interpretations that can be obtained as the union of all interpretations along a path in the tree.

Condition (3) ensures fair, exhaustive rule application, but different orders of application can lead to different chase trees, which can also have different results. Nevertheless, every result is semantically correct in the following sense:

**Fact 2.** Every result of a chase on a rule set $\Sigma$ and database $D$ is a universal model set for $\Sigma$ and $D$.

The pair $(\Sigma, D)$ is chase-terminating if all its chase trees are finite - by König’s Lemma, this is equivalent to all chase results for $(\Sigma, D)$ containing only finite interpretations; this corresponds to all strategy termination. $\Sigma$ is chase-terminating if $(\Sigma, D)$ is chase-terminating for every database $D$; this corresponds to universal termination.

**Turing Machines** We will use (deterministic) Turing machines (TM), denoted as a tuple $M = (Q, \Gamma, \delta, \omega)$, with states $Q$, tape alphabet $\Gamma$ with blank $\_ \in \Gamma$, and transition function $\delta$. $M$ has a distinguished initial state $q_0 \in Q$, and accepting and rejecting halting states $q_A, q_R \in Q$. For all states $q \in Q \setminus \{q_A, q_R\}$ and tape symbols $a \in \Gamma$, there is exactly one transition $(q, a) \rightarrow (r, b, D) \in \delta$. We assume that TM tapes are unbounded to the right but bounded to the left, and that TMs will never attempt to move left on the first position of the tape (this is w.l.o.g., since one can modify any TM to insert a marker at the tape start to recognise this case).

**3 On the Expressivity of Disjunctive Rules**

In this section, we show how to express a homomorphism-closed, decidable query with a disjunctive rule set. This construction will be the basis for finding a chase-terminating set of (deterministic) existential rules. Throughout this section, $\Omega$ is a fixed but arbitrary homomorphism-closed query over signature $\mathcal{S}$, and $M = (Q, \Gamma, \delta)$ is a TM that decides $\Omega$.

To express $\Omega$, we specify five rule sets $R_1 \subseteq R_2 \subseteq R_3 \subseteq R_4 \subseteq R_5$ (see Figures 1–6), which will be explained later. We want to show the following result:

**Theorem 3.** The set $R_5$ of disjunctive existential rules expresses the query $\Omega$.

To do this, we fix an arbitrary database $D$ over $\mathcal{S}$. Theorem 3 then follows from Fact 1 and the next lemma:

**Lemma 4.** There is a universal model set $M$ of $R_5$ and $D$ such that $D \in \Omega$ iff $\text{Goal}(I) \in \Sigma$ for every $I \in M$.

The universal model set $M$ is a complicated structure that we describe step by step, by specifying five sets of interpretations $- I_1, I_2, I_3, I_4$, and $I_5 -$, such that (1) $I_1$ is a universal model set of $R_1, D$ for each $1 \leq i \leq 5$, (2) $|I_1| = |I_2| = |I_3| = |I_4| = |I_5|$, and (3) for each $1 \leq i < j \leq 5$ and each $I \subseteq I_i$, there is exactly one $J \in I_j$ with $I \subseteq J$. Lemma 4 can then be shown using $M = I_5$.

Before dwelling into the details of each rule set and universal model, we give an overview of the construction: $R_1$ constructs all possible linear orders over the nulls in $D$, as well as all possible completions of $D$ with facts built using these nulls; $R_2 \setminus R_1$ extracts successor relations from the linear orders; $R_3 \setminus R_2$ associates to nulls representations of their positions in successor relations; $R_4 \setminus R_3$ encodes all initial TM configurations corresponding to some linear order and completion, and $R_5 \setminus R_4$ simulates the run of the TM on these configurations.

**$R_1$: Linear Order and Database Completion**

$R_1$ serves two distinct purposes: (1) predicates $\text{First}(x, u)$, $\text{Last}(x, u)$, $\text{Eq}(x, y)$, and $\text{LT}(x, y)$ encode representations of possible linear orders over nulls in $D$ (collected in predicate $\text{DbDom}$); and (2) predicates $\text{Inp}_p$ and $\text{NInp}_p$ for each $p \in \mathcal{S}$ explicitly encode positive and negative (absent) facts in $D$. Both purposes require disjunctive reasoning. Possible models include representations of strict, total linear orders (1) and the exact database completion (2), but also models for collapsed orders and inconsistent completions. The latter is not problematic since we consider homomorphism-closed queries.

We define the interpretation set $I_1$ on the set $\Delta = \text{Nulls}(D) \cup \{u_o, u_w\}$, for fresh nulls $u_o, u_w \notin \text{Nulls}(D)$. A (partially collapsed) linear order can be represented by
an ordered partition $\tilde{T} = T_1, \ldots, T_k$ ($k \geq 1$) of $\Delta$ where $u_\text{st} \in T_1$ and $u_\text{end} \in T_k$. Let $\text{Ords}$ be the set of all such $\tilde{T}$, and let $\text{Comps}(\tilde{T})$ be the set of all interpretations with nulls $\Delta$ that are set-minimal among the models of $\mathcal{R}_1$ and $\mathcal{D}$, and that contain the database

$$\{ \text{First}(u) \mid u \in T_1 \} \cup \{ \text{Last}(u) \mid u \in T_k \} \cup \{ \text{Eq}(t,u) \mid 1 \leq i \leq k; t,u \in T_i \} \cup \{ \text{LT}(t,u), \text{NEq}(t,u) \mid 1 \leq i < j \leq k; t \in T_i; u \in T_j \}. $$

By minimality, each $I \in \text{Comps}(\tilde{T})$ contains exactly one of $\{ \text{Ip}_p(\tilde{t}), \text{Nt}_p(\tilde{t}) \}$ for every $\tilde{t} \subseteq \Delta$ with $|\tilde{t}| = Ar(p)$.

**Lemma 5.** $\mathcal{J}_i = \bigcup_{T \in \text{Ords}} \text{Comps}(\tilde{T})$ is a universal model set of $\mathcal{R}_1$ and $\mathcal{D}$.

**Proof Sketch.** We can construct a chase tree for $\mathcal{R}_1$ and $\mathcal{D}$ that prioritises the application of rules in the order of their appearance in Figure 1. The result of that chase is an isomorphic image of every $\tilde{T} \subseteq \Delta$.

Each set $\mathcal{J}_i$ for some $2 \leq i \leq 5$ is obtained as $\mathcal{J}_i = \{ \text{Int}_i(I) \mid I \in \mathcal{J}_{i-1} \}$ for a function $\text{Int}_i$ as defined below. Every $I \in \mathcal{J}_i$ with $1 \leq i \leq 5$ contains a unique interpretation $\text{Seed}(I) \in \mathcal{J}_1$, and there is a unique ordered partition $\text{Order}(I) \in \text{Ords}$ such that $\text{Seed}(I) \in \text{Comps}(\text{Order}(I))$.

**R2: Representative Tree** The purpose of $\mathcal{R}_2$ is to extract successor relations from the transitive linear order $\text{LT}$. Given an ordered partition $\text{Order}(I) = T_1, \ldots, T_k$ of some model $I$ of $\mathcal{R}_1$, $\mathcal{R}_2$ constructs a unique tree structure – defined using predicates $\text{Root}$, $\text{Chi}$ (“child”), and $\text{Leaf}$ – where each path represents a sub-sequence $T_{z_1}, T_{z_2}, \ldots, T_{z_p}$ of $T_1, \ldots, T_k$ with $z_1 = 1$ and $z_p = k$. Unavoidably, some paths will skip some $T_i$, but it suffices for our purposes if one path is complete. The elements of any set $T_j$ are related to the tree nodes that represent $T_j$ by a predicate $\text{Rep}$. Moreover, nodes are related via predicates $\text{In}_{\ell}$ and $\text{Nt}_{\ell}$ that reflect the relations for $\text{In}_{\ell}$ and $\text{Nt}_{\ell}$ that hold between the represented elements (in the database completion of the considered model $I$ of $\mathcal{R}_1$).

Given $I$ with $|\text{Order}(I)| = k$ as above, let $Z$ be the set of all words $z_1 \cdots z_p \in \{1, \ldots, k\}^*$ such that $z_1 = 1$ and $z_i < z_{i+1}$ for all $i \in \{1, \ldots, p-1\}$. Moreover, let $end(z_1 \cdots z_p) := z_p$. Using fresh nulls $\{u_w \mid w \in Z\}$, we define $\text{Tree}(I)$ to be the interpretation

$$\{ \text{Root}(u_1) \} \cup \{ \text{Chi}(u_w, u_{w+z}) \mid w \in Z, 2 \leq z \leq k \} \cup \{ \text{Leaf}(u_w) \mid w \in Z; end(w) = k \} \cup \{ \text{Rep}(x, u_w) \mid w \in Z; x \in \text{Tree}(end(w)) \}. $$

Now $\text{Int}_2(I)$ is the least interpretation that contains $I$ and $\text{Tree}(I)$, and that further satisfies rules (19) and (20). We can extend Lemma 5 as follows. The required universal model set is obtained by any chase that prioritises rule (18).

**Lemma 6.** $\mathcal{J}_2 = \{ \text{Int}_2(I) \mid I \in \mathcal{J}_1 \}$ is a universal model set of $\mathcal{R}_2$ and $\mathcal{D}$.

**R3: Position Binary Encodings** The purpose of $\mathcal{R}_3$ is to associate each node in the tree of $\mathcal{R}_2$ with a binary encoding of its distance from the root (the root starts with “distance” 2 for technical reasons). Encodings start at the least significant bit and always end in 1 (i.e., have no leading 0s). To simplify the updating steps, encodings take the form of a list of TM tapes, represented by a nuxt-connected chain of nulls with unary predicates $\text{S}_0$ and $\text{S}_1$ encoding the symbol at each position. Nodes $u$ relate to the first and last null $t_u$ and $t_v$ of their “tape” through facts $\text{Enc}(u, t_u, t_v)$. Facts $\text{Cpy}(a_{w}, a_{w+1}, b_{w}, b_{w+1})$ are used to create a tape between $b_{w}$ and $b_{w+1}$ that contains a copy of the information on the tape between $a_{w}$ and $a_{w+1}$.

**Predicate** $\text{Cpy}_{+1}$ is analogous, but creates a representation of the successor of the number that is copied.

Consider a model $I$ of $\mathcal{R}_2$ and define the set of sequences $Z$ as before. For $w \in Z$ of length $|w|$, and $b_1 \cdots b_\ell$ by the binary representation of $|w| + 1$, let $\text{EncPos}(w)$ be the database

$$\{ \text{Enc}(u_w, e^1_w, e^\ell_w) \} \cup \{ \text{S}_{b_i}(e^i_w) \mid 1 \leq i \leq \ell \} \cup \{ \text{Nxt}(e^i_w, e^{i+1}_w) \mid 2 \leq i \leq \ell \}. $$

Let $J = I \cup \{ \text{EncPos}(w) \}$. We define $\text{Int}_3(I)$ as the smallest superset of $J$ that satisfies all rules in $\mathcal{R}_3$ while including only the nulls in $J$. $\text{Int}_3(I)$ extends $J$ only by missing $\text{Cpy}$ and $\text{Cpy}_{+1}$ relations, which can be inferred by slightly rewritten rules. For example, rule (22) is satisfied when applying the following rule to $J$:

$$\text{Enc}(u, y_1, y_2) \land \text{Chi}(u, v) \land \text{Enc}(v, z_1, z_2) \rightarrow \text{Cpy}_{+1}(y_1, y_2, z_1, z_2).$$
\[
\begin{align*}
\text{Leaf} (u) & \rightarrow \exists t. \text{Ld}_1(u, t, u) \land \text{Hd}(\bar{p}_i(t)) \quad (31) \\
\text{Ld}_1(u, t, \bar{v}) & \rightarrow \text{Ld}_1(u, t, \bar{v}) \land \text{Hd}(\bar{p}_i(t)) \quad (32) \\
\text{Rdy}_{\bar{p}_i}(u, t, \bar{v}) & \rightarrow \text{Ld}_{\bar{p}_i}(u, t, \bar{v}) \quad (33) \\
\text{Rdy}_{\bar{p}_i}(u, t, \bar{v}) & \rightarrow \text{Rdy}_{\bar{p}_i}(u, t, \bar{v}) \quad (34) \\
\text{Rdy}_r(u, t, \bar{v}) & \land \left( \bigwedge_{i=k+1}^m \text{Root}(v_i) \land \text{Chi}(w, v_k) \right) \rightarrow \text{Ld}_r(u, t, v_1, \ldots, v_{k-1}, w, u, \ldots, u) \quad (35) \\
\text{Rdy}_r(u, t, \bar{v}) & \land \left( \bigwedge_{i=1}^m \text{Root}(v_i) \right) \rightarrow \text{Ld}_{r+1}(u, t, u, \ldots, u) \quad (36) \\
\text{Rdy}_r(u, t, \bar{v}) & \land \left( \bigwedge_{i=1}^m \text{Root}(v_i) \right) \rightarrow \text{S}_r(t) \land \text{End}(t) \quad (37) \\
\text{Ld}_p(u, t, \bar{v}) & \land \exists \bar{p}_i \rightarrow \text{Rdy}_p(u, t, \bar{v}) \quad (38)
\end{align*}
\]

Figure 5: Some rules of \(\mathcal{R}_4\), to be instantiated for all \(1 \leq j \leq n-1\), \(1 \leq k \leq \ell \leq m\), and \(p \in S\).

All other rules can be rewritten analogically, since every existentially quantified variable is used in unique ways with predicates other than \(\text{Cpy}\) and \(\text{Cpy}_r\).

For every \(\mathcal{I} \in \mathcal{I}_2\), we show that \(\text{Int}_I(\mathcal{I})\) is isomorphic to a result of the chase on \(\mathcal{R}_3\) and \(\mathcal{I}\). The next result then follows from Lemma 6.

**Lemma 7.** \(\mathcal{I}_3 = \{ \text{Int}_I(\mathcal{I}) \mid \mathcal{I} \in \mathcal{I}_2\}\) is a universal model set of \(\mathcal{R}_3\) and \(\mathcal{D}\).

**\(\mathcal{R}_4\): Initial TM Configuration** For each leaf in the tree of completions, \(\mathcal{R}_4\) creates the representation of an initial TM configuration. The tape is again represented by a \(\text{lxt}\)-chain, using further unary predicates \(S_0, S, S_u\), and \(S_p\) (for all \(p \in S\)) for additional tape symbols. \(\text{Hd}_{\bar{p}_i}\) marks the TM’s starting position and initial state \(q_0\), and \(\text{End}\) the end of the tape.

Let \(m\) be the maximal arity of predicates in \(S\). We require that there is some \(\bar{n} > 0\) such that \(S\) contains exactly \(n\) predicates \(p_1, \ldots, p_n\) of arity \(i\), for every \(1 \leq i \leq m\). This is without loss of generality, except for the exclusion of nullary predicates. Our results do not depend on this restriction, but it helps to simplify the presentation of our main ideas.

To serialise the data as a tape, we iterate over all predicate arities \(1 = \ell, \ldots, m\) and over all lists \(\bar{v}\) of tree nodes with length \(\ell\). In this process, \(\text{Ld}_1(u, t, \bar{v})\) expresses that, while encoding the leaf \(u\), after constructing the tape until position \(t\), we continue serialising \(\ell\)-ary predicate data for arguments \(\bar{v}\). Analogously, \(\text{Rdy}_r(u, t, \bar{v})\) means that this was completed at tape position \(t\). Similar predicates \(\text{Ld}_p\) and \(\text{Rdy}_p\) are used to consider a specific predicate \(p \in S\) during this process. The rules in Figure 5 start the serialisation (31), proceed over all predicates (32)--(34), iterate over parameter vectors (35) and arities (36), and finally end the tape (37).

Absent facts do not need to be serialised (38), while present facts can be treated by copying the encodings for each of their parameters (29) and (30). In the latter, \(\text{Ld}\) states that a specific argument is serialised between two given tape positions.

The resulting TM tapes serialise facts \(\text{In}_r(\bar{u})\) as introduced by \(\mathcal{R}_2\), i.e., where \(\bar{u}\) are nodes in the representative tree. Given a model \(\mathcal{I} \in \mathcal{I}_3\) with some \(\text{Leaf}(u_w) \in \mathcal{I}\), let \(\text{branch}(u_w)\) be the set of all nodes \(u_w\) on the branch of \(u_w\), i.e., all nulls \(u_w\) where \(w\) is a prefix of \(w\). Elements of \(\text{branch}(u_w)\) are totally ordered by setting \(u_{w_1} \prec u_{w_2}\) if \(|w_1| > |w_2|\). Predicates are totally ordered by setting \(p_i \prec p_j\) if either \(a < b\) or both \(a = b\) and \(i < j\). We can then order facts as \(p(\bar{u}) \prec q(\bar{v})\) if \(\bar{u}, \bar{v} \subseteq \text{branch}(u_w)\) and \((\bar{p}, \bar{u})\) is lexicographically before \((\bar{q}, \bar{v})\).

Now let \(\text{branchD}(\mathcal{I}, u_w) = \{ p(\bar{u}) \mid \text{In}_r(\bar{u}) \in \mathcal{I}, \bar{u} \subseteq \text{branch}(u_w)\}\) denote the set of all facts on the branch with leaf \(u_w\), and let \(\text{branchTape}(\mathcal{I}, u_w)\) denote the TM tape serialisation (as defined in Section 2) of \(\text{branchD}(\mathcal{I}, u_w)\) according to the total order \(\prec\) and representing each node \(u_\alpha\) by the binary representation of \(|\alpha| + 1\) as before. Given \(\mathcal{S} = \text{branchTape}(\mathcal{I}, u_w)\), let \(\text{startConf}(\mathcal{I}, u_w)\) be the following interpretation:

\[
\begin{align*}
\{ \text{Ld}_1(u_w, t^1_{w}, u_w), \text{Hd}_{\bar{p}_i}(t^1_w), \text{End}(t^1_{w} S^1) \} \cup \\
\{ \text{Nxt}(t^1_{w}, t^2_{w}) \mid 2 \leq j \leq S^1 + 1 \} \cup \\
\{ \text{S}_a(t^1_{w}) \mid 1 \leq j \leq S^1, a = S^1[j] \} \cup \{ \text{S}_r(t^1_{w} S^1) \}
\end{align*}
\]

Let \(J\) be the extension of \(\mathcal{I}\) with \(\text{startConf}(\mathcal{I}, u_w)\) for every \(\text{Leaf}(u_w) \in \mathcal{I}\). We define \(\text{Int}_I(\mathcal{I})\) to be the smallest superset of \(J\) that satisfies all rules in \(\mathcal{R}_4\) while including only the nulls in \(J\). As in the case of \(\text{Int}_I(\mathcal{I})\), the missing relations can easily be inferred using the original rules or, for (29) and (30), with simple rewritings thereof.

**Lemma 8.** \(\mathcal{I}_4 = \{ \text{Int}_I(\mathcal{I}) \mid \mathcal{I} \in \mathcal{I}_3\}\) is a universal model set of \(\mathcal{R}_4\) and \(\mathcal{D}\).

**\(\mathcal{R}_5\): TM Run** The purpose of \(\mathcal{R}_5\) is to simulate the run of the deterministic TM \(\langle Q, \Gamma, \delta \rangle\) on each of the initial tapes created by \(\mathcal{R}_4\). We continue to use predicate \(\text{lxt}\) for neighbouring tape cells (augmented with its transitive closure \(\text{lxt}^+\)), \(S_b\) to encode tape symbols \(b \in \Gamma\), and \(\text{Hd}\) to encode head position and current state \(q \in Q\). Predicate \(\text{Stp}\) connects tape cells in each configuration to the corresponding tape cells in the next configuration (provided the TM performs another step). The rules in Figure 6 are a standard TM encoding, with the slight exception of rule (43), which adds a new blank tape cell in each step (even if not used by the TM). Our rules use the assumptions on TMs in Section 2.

Consider some \(\mathcal{I} \in \mathcal{I}_3\). It is easy and only mildly laborious to define interpretations \(\text{Run}(u_w)\) that represent all successor configurations of the starting configuration \(\text{startConf}(\mathcal{I}, u_w)\), appropriately connected with \(\text{Stp}\) and
4 Ensuring Chase Termination

While the rules in Section 3 are semantically correct, the disjunctive chase may not terminate on them. Many known fragments of existential rules can guarantee chase termination, including for expressive cases where termination might be exponential (Carral et al. 2019), but they are not applicable to our case, since the runtime of TMs that decide a query can in general not be bounded by any elementary function. Indeed, we rely on the TM to stop “naturally”, by virtue of being a decider. Nevertheless, our rules lead to infinite chase trees, e.g., if the disjunctive guessing of LT leads to a cycle, which enables rule (16) to create an infinite path in the representation tree. We will now show that this can be avoided:

Theorem 12. Every homomorphism-closed decidable query is expressed by a set of disjunctive rules that is chase-terminating for all databases over the schema of the query.

To show this, we refine and generalise the “emergency brake” technique of Krötzsch, Marx, and Rudolph (2019), and re-formulate it as a general rule set transformation. This not only yields a generic method that is of independent interest, but it also allows us to address potential termination problems in our prior modelling.

Definition 3. Consider a rule set \( \Sigma \) and a nullary predicate \( \text{Halt} \) that does not occur in \( \Sigma \). For every predicate \( p \) in \( \Sigma \), let \( \overline{p} \) be a fresh predicate of the same arity, and, for any formula \( \psi \), let \( \overline{\psi} \) be \( \psi \) with all predicates \( p \) replaced by \( \overline{p} \). Now the set \( \text{brake}(\Sigma, \text{Halt}) \) consists of the following rules:

\[
\overline{\exists v.\text{Brake}(v)} \quad \overline{\forall x.\text{Real}(x)} \quad \overline{\forall y.\text{Real}(y)}
\]

For every rule \( r : \beta[x] \rightarrow \bigwedge_{i=1}^k \overline{\exists y_i} \eta_i[x_i, y_i] \):

\[
\overline{\beta[x]} \wedge \text{Brake}(v) \rightarrow \bigvee_{i=1}^k \overline{\text{B}_p(x_i)} \wedge \overline{\eta_i[x_i, y_i] \rightarrow v} \wedge \bigwedge_{x \in x_i} \text{Real}(x) \wedge \bigwedge_{y \in y_i} \text{Real}(y)
\]

where \( \overline{\eta_i[x_i, y_i]} \rightarrow v \) is \( \eta_i \) with each variable \( y \) in \( y_i \) replaced by \( v \), and Brake, Real, and all \( \overline{B}_p \) are fresh predicates with arities as indicated.

Note that \( \text{brake}(\Sigma, \text{Halt}) \) does not define rules to derive \( \text{Halt} \), and indeed the transformation largely preserves the models of \( \Sigma \) in the following sense:

Lemma 13. Consider a rule set \( \Sigma \) and database \( D \) over predicates that occur in \( \Sigma \). For every model \( I \) of \( \text{brake}(\Sigma, \text{Halt}) \) and \( D \), the set \( I^- = \{ p(\overline{v}) \mid p(\overline{v}) \in I, p \text{ occurs in } \Sigma \} \) is a model of \( \Sigma \) and \( D \), and every model \( J \) of \( \Sigma \) and \( D \) is of this form.

Proof. Consider a rule \( r \in \Sigma \) as in Definition 3, and let \( \sigma \) be a substitution such that \( \sigma(\beta) \subseteq I^- \). Then we can apply rules (52), (53), and finally (51) to derive \( \sigma(\overline{\eta_i}) \subseteq I^- \) for a suitable extension \( \sigma' \) of \( \sigma \). Hence \( I^- \models \Sigma \).

Conversely, let \( J \models \Sigma \). A model \( I \) of \( \text{brake}(\Sigma, \text{Halt}) \) can be found by adding, for each matching body \( \sigma(\beta) \subseteq I^- \)
of rule $\rho$, an atom $\sigma(B_\rho^i(\bar{x}))$ for some $i$ such that $\sigma'(\eta_i) \subseteq J$ for an extension $\sigma'$ of $\sigma$. To obtain the required model $I$ of $\text{brake}(\Sigma, \text{Halt})$, it remains to add facts $\text{Brake}(b)$ for a fresh null $b$, $\sigma(\eta_i)[\bar{x}_i, y_i \mapsto b]$ as in (52) for every $\sigma(B_\rho^i(\bar{x})) \in I$, and $\text{Real}(n)$ for every $p(i) \in J$ and $n \in i$.

For $\text{brake}(\Sigma, \text{Halt})$ to be useful, we need to add rules that can “pull the brake” by deriving $\text{Halt}$. Doing so stops the chase in the following sense:

Lemma 14. Consider a rule set $\Sigma$, a database $D$ over predicates that occur in $\Sigma$, and a set $\Pi$ of rules of the form $\beta \rightarrow \text{Halt}$ where $\beta$ only uses predicates in $\Sigma$. If $I$ is the label of a node in a chase tree for $\Sigma \cup \Pi$ and $D$ such that $\text{Halt} \in I$, then the tree starting at the node of $I$ is finite.

Proof. Since $\text{Halt} \in I$, there is a substitution $\sigma$ such that $(\rho(50), \sigma)$ is applicable (for $\rho(50)$ in (50)). By fairness, $\text{Real}(\sigma(x))$ will be derived at some depth of the tree. From this depth on, no rule of form (53) is applicable: given $\text{Real}(\sigma(x))$, the rules of head of rules of form (52) already satisfies the head of the rule (53) that could be applied to a newly derived atom for $B^\rho_i$. Rules other than (53) do not contain existential quantifiers thus can only be applied a finite number of times before the chase on this part of the tree terminates.

If $\text{Halt}$ is derived, the semantic correspondence of Lemma 13 is weakened, but suffices to preserve entailments:

Lemma 15. Consider $\Sigma$, $D$, and $\Pi$ as in Lemma 14. For every model $I$ of $\text{brake}(\Sigma, \text{Halt}) \cup \Pi$ and $D$, $I^{-}$ (as in Lemma 13) is a model of $\Sigma$ and $D$.

Proof. This is immediate from Lemma 13 and the fact that every model of $\text{brake}(\Sigma, \text{Halt}) \cup \Pi$ and $D$ is a model of $\text{brake}(\Sigma, \text{Halt})$ and $D$.

Having established the key properties of the emergency brake construction, we can now apply it to show Theorem 12. Given the rule set $\mathcal{R}_S$ as defined for a query $\Omega$ in Section 3, let $\mathcal{R}_S$ denote the extension of $\text{brake}(\mathcal{R}_S, \text{Halt})$ with the following rules:

\[ \text{In}_p(x) \land \text{NIn}_p(x) \rightarrow \text{Halt} \quad (54) \]
\[ \text{LT}(x, y) \rightarrow \text{Halt} \quad (55) \]
\[ \text{First}(x) \land \text{LT}(x, y) \rightarrow \text{Halt} \quad (56) \]
\[ \text{LT}(x, y) \land \text{First}(y) \rightarrow \text{Halt} \quad (57) \]

Lemma 16. $\mathcal{R}_S$ expresses the query $\Omega$.

Proof. For a database $D$ over $\Sigma$, let $\mathcal{M}$ be the universal model set constructed in Section 3. If $D \in \Omega$, then $\mathcal{R}_S, D \models \text{Goal}$ by Theorem 3. Then $\mathcal{R}_S, D \models \text{Goal}$ since any model of $\mathcal{R}_S$ and $D$ must contain $\text{Goal}$ by Lemma 15.

Conversely, if $D \notin \Omega$, then there is $U \in \mathcal{M}$ with $\text{Goal} \notin U$. By Lemma 13, there is a model $I$ of $\text{brake}(\mathcal{R}_S, \text{Halt})$ with $I^- = U$, and hence $\text{Goal} \notin I$. By construction of $\mathcal{M}$, none of the rules (54)-(57) applies to $U$, and hence $I$ is also a model of $\mathcal{R}_S$, i.e., $\mathcal{R}_S, D \not\models \text{Goal}$.

Lemma 17. $\mathcal{R}_S$ is chase-terminating for all databases over the schema $\mathcal{S}$ of the query $\Omega$.

Proof. Consider a chase over $\mathcal{R}_S$ and input database $D$. Chase branches where $\text{Halt}$ is eventually part of a node label terminate by Lemma 14. Let $b$ denote any branch of the chase where $\text{Halt}$ is not derived, and let $I$ be the union of all node labels on that branch. We want to show that $I$ (and hence $b$) is finite.

By Lemma 13, $I \models R_1$. Moreover, since $\text{Halt} \notin I$, rules (54)-(57) are not applicable to $I$. Both properties together suffice to show that the set $I_{R_1} = \{ p(i) \in I \mid p \text{ is a predicate in } R_1 \}$ is an element of $H_1$ defined in Section 3.

Since the predicates in rule bodies of $R_1$ do not occur in any rule head in $R_5 \setminus R_1$, we can conclude without loss of generality (and without affecting chase termination), that the corresponding rules of $\text{brake}(R_1, \text{Halt}) \subseteq \mathcal{R}_S$ have been applied first. This shows that $I$ is equal to the result of a chase with non-disjunctive rules $\mathcal{R}_S \setminus \text{brake}(R_1, \text{Halt})$ on a database $D_{R_1} \in I_1$. The claim follows by noticing that any such chase must terminate: this was shown in Section 3, where we described a deterministic process of defining the elements in the universal model set $\mathcal{M}$ from those in $I_1$. Each steps in this construction is fully determined and introduces isomorphic sets of nulls irrespective of the order of rule applications. The only exception are application rules (15), (16), and (18). For example, given facts $\text{First}(n_1), \text{First}(n_2)$, and $\text{Eq}(n_1, n_2)$, the standard model of Section 3 contains one fact $\text{Root}(u_1)$ with $\text{Rep}(n_1, u_1)$ and $\text{Rep}(n_2, u_1)$, which can be obtained using (15) on $n_1$ and (18). If we apply (15) to both $n_1$ and $n_2$ before applying (18), we obtain two distinct $\text{Root}(u_1)$ and $\text{Root}(u_1')$. Similar variations can occur with other tree nodes if (16) is applied before (18). If is easy to see that this does not endanger termination, but merely leads to several isomorphic paths in the representation tree.

Together, Lemmas 16 and 17 show Theorem 12.

5 Removing Disjunctions

Our main result is that any decidable homomorphism-closed query is expressible by a chase-terminating existential rule set. To conclude the proof of this statement, we remove the disjunction from the rule set $\mathcal{R}_S$ of Section 4. We present this as a general technique of expressing disjunctive Datalog using existential rules, which is also of independent interest.

For a rule set $\Sigma$, the input schema $S_{in}(\Sigma)$ is the set of all predicates in $\Sigma$ that do not occur in any rule head. We focus on rule sets that can be split into a disjunctive part and an existential part, such that it is admissible to completely apply the disjunctive rules first, and the existential ones afterwards:

Definition 4. A split of a set $\Sigma$ of disjunctive existential rules consists of a set $\Sigma_1$ of disjunctive Datalog rules and a set $\Sigma_2$ of existential rules, such that $\Sigma = \Sigma_1 \cup \Sigma_2$ and:

For every database $D$ over $S_{in}(\Sigma)$, and for every chase result $\mathcal{M}$ over $\langle \Sigma, D \rangle$, there is a chase result $\mathcal{M}_1$ over $\langle \Sigma_1, D \rangle$, such that $\mathcal{M}_1 = \{ C_2 \mid I \in \mathcal{M}_1 \}$ where each $C_2$ is the (unique) interpretation resulting from some chase over $\langle \Sigma_2, I \rangle$.
\( \exists w. \text{Init}(w) \land \text{Done}(w) \land \text{Empty}(w) \)  
\( \text{Done}(w) \land \text{Init}(w) \land p(x) \rightarrow \exists w'. \text{Ins}_p(x, w, w') \land \text{Subs}(w', w') \land \text{Init}(w') \)  
\( \text{Done}(w) \land \bigwedge_{p(x) \in P} \text{Ins}_p(x, w, w) \rightarrow \exists w_1. \text{Ins}_p(x', w_1, w_1) \land \text{Subs}(w_1, w_1) \)  
\( \text{Done}(w) \land \bigwedge_{p(x) \in P} \text{Ins}_p(x, w, w) \rightarrow \exists w_2. \text{Ins}_p(x', w_2, w_2) \land \text{Subs}(w_2, w_2) \)  
\( \text{Ins}_p(x, w_0, w_1) \land \text{Subs}(w_1, w_2) \rightarrow \text{Ins}_p(x', w_2, w_2) \land p'(x', w_2) \land \text{Subs}(w_0, w_2) \)  
\( \text{Empty}(w) \land \text{Subs}(w, w) \rightarrow \text{Done}(w) \)

\begin{align*}
\text{Done}(w) & \land \bigwedge_{p(x) \in P} P'(x, w) \rightarrow \exists \vec{y}. \bigwedge_{q(y) \in \eta} \text{q}(\vec{y}, w) \\
\text{Goal}'(w) & \rightarrow \text{Acc}(w)  \\
\text{Ins}_p(x_1, w_1, w_1) & \land \text{Acc}(w_1) & \text{Ins}_p(x_2, w_2, w_2) & \land \text{Acc}(w_2) & \bigwedge_{p(x) \in P} \text{Ins}_p(x, w, w) & \rightarrow \text{Acc}(w)  \\
\text{Init}(w) & \land \text{Acc}(w) \rightarrow \text{Goal}
\end{align*}

**Lemma 18.** Consider a rule set \( \Sigma \) with split \((\Sigma_1, \Sigma_2)\). There is a set \( \Sigma' \) of existential rules, such that, for every database \( D \) over \( S_m(\Sigma) \), we have:

1. \( D, \Sigma \models \text{Goal} \) iff \( D, \Sigma' \models \text{Goal} \), and
2. if \((\Sigma_2, D_2)\) is chase-terminating for every database \( D_2 \) over \( S_m(\Sigma_2) \), then \((\Sigma', D)\) is also chase-terminating.

To construct this set \( \Sigma' \), we assume w.l.o.g. that all disjunctive rules have exactly two disjuncts in the head. We define \( \Sigma' \) as the union of sets \( \Sigma'_1, \Sigma'_2, \) and \( \Sigma'_3 \) as shown in Figures 7, 8, and 9, which we explain below.

\( \Sigma'_1 \) uses a technique for modelling sets with chase-terminating existential rules (Krötzsch, Marx, and Rudolph 2019, Fig. 2). We adapt this to sets of ground atoms, called worlds and denoted by variables \( w \) in the figures. Facts \( \text{Ins}_p(t, w, w') \) express that world \( w' \) is obtained by adding \( p(t) \) to world \( w \). In particular, \( \text{Ins}_p(t, w, w) \) states that \( p(t) \) is in \( w \), and we define \( \text{world}(w) = \{ p(\bar{a}) \mid \text{Ins}_p(\bar{a}, w, w) \in I \} \) for any interpretation \( I \). Worlds are created by adding database facts (59) or by applying rules to existing worlds (60)–(61). Worlds containing only database facts are marked with \( \text{Init} \). Predicate \( \text{Subs} \) defines the subset relation on worlds. Rules (62)–(63) copy all prior facts to a new world before marking it \( \text{Done} \).

**Proposition 19.** \( \Sigma'_1 \) is chase-terminating and for every \( D \) over \( S_m(\Sigma) \), the (unique) interpretation \( I \) resulting from some chase over \( \Sigma'_1 \) and \( D \) is such that:

- if \( p(\bar{a}) \in D \) and \( \text{Done}(w) \in I \), there exists \( w' \) such that \( \text{Ins}_p(\bar{a}, w, w') \in I \) and \( \text{world}(w') = \text{world}(w) \cup \{ p(\bar{a}) \} \);

- if \( \rho \in \Sigma_1 \) is applicable to \( \text{world}(w) \), creating \( \text{p}_1(\bar{a}) \) or \( \text{p}_2(\bar{b}) \), there exists \( w_1 \) and \( w_2 \) such that \( \{ \text{Ins}_p(\bar{a}, w, w_1), \text{Ins}_p(\bar{b}, w, w_2) \} \subseteq I \), \( \text{world}(w_1) = \text{world}(w) \cup \{ p_1(\bar{a}) \} \) and \( \text{world}(w_2) = \text{world}(w) \cup \{ p_2(\bar{b}) \} \).

Note that we cannot distinguish worlds that are not containing all database facts, and that some worlds may contain more facts than needed to satisfy all disjunctive heads.

\( \Sigma'_2 \) now simulates the application of rules from \( \Sigma_2 \) in any of the worlds. Computations relative to different worlds are independent from each other. Finally, \( \Sigma'_3 \) aggregates results from all worlds: a world is accepting \( \text{Acc} \) if either \( \text{Goal} \) is derived locally (65) or it has two successor worlds for a disjunctive rule that are both accepting (66). \( \text{Goal} \) is a consequence if any initial world is accepting (67). This finishes the construction of \( \Sigma' \) as the main ingredient for proving Lemma 18.

Finally, we can apply Lemma 18 to \( \mathcal{R} = \text{brake}(\mathcal{R}_5, \text{Halt}) \cup \Pi \) from Section 4, where \( \Pi \) denotes rules (54)–(57). Intuitively, a possible split is \( \text{brake}(\mathcal{R}_1, \text{Halt}) \) and \( \text{brake}(\mathcal{R}_5 \setminus \mathcal{R}_1, \text{Halt}) \cup \Pi \). Formally, however, \( \text{brake}(\mathcal{R}_1, \text{Halt}) \) is not disjunctive Datalog due to existential rules (2), (3), and (49). However, our result easily extends to such rules with empty body: we can just add them to \( \Sigma'_1 \) and treat their inferences like facts from the initial database. The other properties of Definition 4 are easy to verify. The fact that both rule sets have some common rules, such as (50), is no concern. Finally, it remains to argue termination for \( \Sigma_2 \) as required for item (2) in Lemma 18. This is slightly stronger than Lemma 17 since we must also consider databases that use some inferred predicates of \( \mathcal{R}_1 \). However, the proof of Lemma 17 and the emergency brake technique in general served the main purpose of safeguarding against problematic structures among the inferred predicates of \( \mathcal{R}_1 \), and it is not hard to see that this already showed what we require here. Combining all of our insights, we finally obtain:

**Theorem 20.** Chase-terminating existential rules capture the class of all decidable homomorphism-closed queries.

### 6 Limitations of Semi-Decidable Languages

A query language \( \mathcal{F} \) over a schema \( S \) is a function from a set \( L \) to \( 2^{\mathcal{F}(S)} \), where \( \mathcal{F}(S) \) is the set of all databases over schema \( S \). We say that \( \mathcal{F} \) is semi-decidable if membership to \( L \) is semi-decidable, and that its query answering problem is decidable if there exists a TM \( M_\mathcal{F} \) that takes as input some
\((l,D) \in (L \times \mathcal{D}_S)\) and decides whether \(D \in \mathcal{F}(l)\).

The set of chase-terminating existential rule sets is a query language that is not semi-decidable (Grathwohl and Onet 2018) and for which the query answering problem is decidable (by running the chase). In fact, we show that one cannot find a semi-decidable query language with similar properties.

**Theorem 21.** There are no semi-decidable query languages that (i) express all decidable, homomorphism-closed queries and (ii) for which query answering is decidable.

To show this result, we define a set \(M\) of TMs (cf. Definition 5), show that \(M\) can be enumerated up to equivalence if there is a semi-decidable language that satisfies (i) and (ii) above (cf. Lemma 22), and finally prove that the consequence of this implication does not hold (cf. Lemma 23).

**Definition 5.** Consider the set \(M\) of all TMs \(M\) such that:

(i) The TM \(M\) halts on all inputs. (ii) If \(M\) accepts some word \(w\), then \(w\) corresponds to a database over schema \(\{\text{ed}\}\). (iii) Consider some words \(w\) and \(v\) that correspond to some \(D\) and \(E\) in \(\mathcal{D}_{\{\text{ed}\}}\), respectively. If \(M\) accepts \(w\) and there is a homomorphism \(h : D \to E\), then \(M\) accepts \(v\).

Intuitively, \(M\) is the set of all deciders that solve homomorphism-closed queries over databases in \(\mathcal{D}_{\{\text{ed}\}}\).

**Lemma 22.** If there is a semi-decidable query language \(\mathcal{F}\) that satisfies (i) and (ii) in Theorem 21, then \(M\) is enumerable up to equivalence.

**Proof.** If there is a language such as \(\mathcal{F}\), then there is an enumerator \(P\) for \(L\) that prints out a sequence \(l_1, l_2, \ldots\) and a decider \(M_d\) that can be used to check if \(D \in \mathcal{F}(l)\) for each \((l,D) \in (L \times \mathcal{D}_{\{\text{ed}\}})\). For each \(i \geq 1\), let \(M_i\) be the TM that, on input \(w\), performs the following computation: if \(w\) corresponds to a database \(D \in \mathcal{D}_{\{\text{ed}\}}\) and \(M_d\) accepts \((l_i,D)\), then accept; otherwise, reject. By modifying \(P\) we can define an enumerator that prints out the sequence \(M_1, M_2, \ldots\), which contains \(M\) up to equivalence.

**Lemma 23.** The set \(M\) is not enumerable up to equivalence.

**Proof Sketch.** Assume that there is an enumerator that outputs a sequence \(M_1, M_2, \ldots\) that includes \(M\) up to equivalence. We obtain a contradiction by defining a sequence \(D_1, D_2, \ldots\) of databases and a TM \(M_d\) that diagonalises over \(M_1, M_2, \ldots\) and \(D_1, D_2, \ldots\). Namely, for each \(i \geq 1\), let \(D_i = \{\text{ed}(u_1, u_2), \ldots, \text{ed}(u_{i+1}, u_1)\}\) where \(p_{i+1}\) is the \((i+1)\)-th prime. Moreover, \(M_d\) is the TM that, on input \(w\), performs the computation: (1) Reject if \(w\) does not correspond to some \(D \in \mathcal{D}_{\{\text{ed}\}}\). (2) Reject if \(D\) can be hom-embedded into a path over ed. (3) Accept if \(\text{ed}(u, w) \in D\) for some null \(u\). (4) If there is some \(i \geq 1\) such that there are less nulls in \(D_i\) than in \(D\), the TM \(M_i\) accepts some serialization that corresponds to \(D_i\), and there is a homomorphism \(h : D \to D_i\); then reject. Otherwise, accept.

### 7 Discussion and Conclusion

In this paper, we have established a characterization of all decidable homomorphism-closed Boolean queries. We showed that these are exactly the chase-terminating existential rule queries, that is, queries that can be expressed by a set of (non-disjunctive) existential rules for which the standard chase universally terminates irrespective of the order of rule applications (as long as it is fair).

By its nature, our result immediately shows that various extensions of our framework do not increase its expressivity:

**Theorem 24.** Chase-terminating existential rule queries have the same expressivity as

1. existential rule queries with guaranteed existence of some finite chase tree (for every database),
2. existential rule queries for which the chase terminates according to some fair strategy (such as datalog-first),
3. core-chase-terminating existential rule queries,
4. disjunctive chase-terminating existential rule queries.

**Proof.** (3) Standard-chase termination implies core-chase termination. On the other hand, core chase termination implies decidability and thus our result applies. (1) and (2) Standard-chase termination implies these weaker form of guarantees, which themself imply core chase termination. (4) Obviously, every (non-disjunctive) existential rule set is a special case of a disjunctive one and for this special case, disjunctive chase termination coincides with termination of the (non-disjunctive) standard chase. On the other hand, disjunctive existential rule queries are also closed under homomorphisms, and disjunctive universal chase termination obviously implies decidability. So our result applies.

However, the applicability of our result does not stop at (syntactic) extensions of our framework, as it applies to arbitrary query languages and querying formalisms of different types. In particular we would like to stress the relationship to the very comprehensive existential rules fragment of bounded treewidth sets (bts) of rules (Baget et al. 2011a) that is not chase-terminating and encompasses a plethora of well-known existential rule fragments with decidable query entailment, including guarded (Calì, Gottlob, and Kifer 2008), frontier-guarded (Baget et al. 2011a), and glut-guarded existential rules (Krötzsch and Rudolph 2011), as well as greedy bts (Baget et al. 2011b):

**Theorem 25.** Let \(\Sigma\) be a bounded-treewidth set of rules and \(Q\) a conjunctive query. There is a chase-terminating set \(\Sigma_Q\) of existential rules such that \(\Sigma,\Sigma_Q \models \text{Q}\).

While possibly surprising, this is a straightforward consequence of decidability of conjunctive query entailment from bts and of homomorphism-closedness of existential rule queries in general. Note, however, that every \(Q\) would give rise to a different \(\Sigma_Q\). In fact, asking for a “uniform” chase-terminating existential rules set \(\Sigma'\) satisfying \(\Sigma,\Sigma' \models \text{Q}\) if \(\Sigma,\Sigma' \models \text{Q}\) would change the game (Zhang, Zhang, and You 2015). Such a set will not exist in all cases.

While our result addresses many of the open questions regarding expressivity of the terminating chase (Krötzsch, Marx, and Rudolph 2019) an important avenue for future work is to investigate potential differences when it comes to the corresponding computational complexities. We deem it likely that not all of the discussed chase variants give rise to worst-case optimal computations.

References

A Proofs for Section 3

In this section, we prove the claims made in Section 3. In particular, besides proving Lemmas 5, 6, 7, 8, 9, 10, and 11, we show Lemma 26 from which the next claims (given in the order they occur in the section) follow.

1. $|\mathcal{I}_1| = |\mathcal{I}_2| = |\mathcal{I}_3| = |\mathcal{I}_4| = |\mathcal{I}_5|.$

2. For each $1 \leq i < j \leq 5$ and each $\mathcal{I} \in \mathcal{I}_i$, there is exactly one $\mathcal{J} \in \mathcal{I}_j$ with $\mathcal{I} \subseteq \mathcal{J}$.

3. Every $\mathcal{I} \in \mathcal{I}_i$ with $1 \leq i \leq 5$ contains a unique interpretation $\text{Seed}(\mathcal{I}) \in \mathcal{I}_1$, and there is a unique ordered partition $\text{Order}(\mathcal{I}) \in \text{Ords}$ such that $\text{Seed}(\mathcal{I}) \in \text{Compls}(\text{Order}(\mathcal{I}))$.

Recall that $\Delta = \text{Nulls}(\mathcal{D}) \cup \{u_\alpha, u_\omega\}$. We will call a $\mathcal{D}$-order a database over schema \{First, Last, LT, Eq, NEq\} and nulls from $\Delta$, and a $\mathcal{D}$-completion a database over schema \{In_p, NIn_p | $p \in S\} and nulls from $\Delta$. We say that a $\mathcal{D}$-completion is complete if (i) it includes $\{\text{In}_p(\bar{i}) | p(\bar{i}) \in \mathcal{D}\}$ and (ii) for every $p \in S$ and tuple $\bar{i} \subseteq \Delta$ of matching arity, it contains exactly one of $\{\text{In}_p(\bar{i}), \text{NIn}_p(\bar{i})\}$.

**Lemma 26.** There is a one-to-one correspondence between the interpretations in $\mathcal{I}_i (1 \leq i \leq 5)$ and the pairs of the form $(\bar{T}, \mathcal{F}_D)$, where $\bar{T} = T_1, \ldots, T_k \in \text{Ords}$ is an ordered partition of $\Delta$ with $u_\alpha \in T_1$ and $u_\omega \in T_k$, and $\mathcal{F}_D$ is a complete $\mathcal{D}$-completion. More precisely:

- An interpretation $\mathcal{I} \in \mathcal{I}_1$ corresponds to a pair $(\bar{T}, \mathcal{F}_D)$ iff $\mathcal{I}$ is the union of the following databases:
  - $\mathcal{D} \cup \{\text{DbDom}(t) | t \in \Delta\}.$
  - the $\mathcal{D}$-order corresponding to $\bar{T}$: $\{\text{First}(t) | t \in T_1\} \cup \{\text{Last}(t) | t \in T_k\} \cup \{\text{Eq}(t, u) | 1 \leq i \leq k; t, u \in T_i\} \cup \{\text{LT}(t, u), \text{NEq}(t, u), \text{NEq}(u, t) | 1 \leq i < j \leq k; t \in T_i, u \in T_j\}$, and
  - $\mathcal{F}_D$.

- An interpretation $\mathcal{I} \in \mathcal{I}_i (2 \leq i \leq 5)$ corresponds to $(\bar{T}, \mathcal{F}_D)$ iff it includes some $\mathcal{I} \in \mathcal{I}_1$ that corresponds to $(\bar{T}, \mathcal{F}_D)$.

In particular, it follows that every $\mathcal{I} \in \mathcal{I}_i$ with $1 \leq i \leq 5$ contains a unique interpretation $\text{Seed}(\mathcal{I}) \in \mathcal{I}_1$, and there is a unique ordered partition $\text{Order}(\mathcal{I}) \in \text{Ords}$ such that $\text{Seed}(\mathcal{I}) \in \text{Compls}(\text{Order}(\mathcal{I}))$.

**Proof.** The correspondence between interpretations in $\mathcal{I}_1$ and pairs of the form $(\bar{T}, \mathcal{F}_D)$ is well defined because $\mathcal{I}_1 = \bigcup_{\mathcal{I} \in \text{Ords}} \text{Compls}(\bar{T})$ where $\text{Compls}(\bar{T})$ is the set of all minimal models of $\mathcal{R}_1$ and $\mathcal{D}$ that contain the $\mathcal{D}$-order corresponding to $\bar{T}$. In particular, every $\mathcal{I} \in \mathcal{I}_1$ must include a complete $\mathcal{D}$-completion to satisfy (14) and (4), and by minimality $\mathcal{I}$ does not include any set of the form $\{\text{In}_p(\bar{i}), \text{NIn}_p(\bar{i})\}$. Moreover, by minimality, $\mathcal{I}$ does not contain any other atom over predicates $\{\text{First}, \text{Last}, \text{LT}, \text{Eq}, \text{NEq}\}$.

Each $\mathcal{I}_i (2 \leq i \leq 5)$ is obtained from $\mathcal{I}_{i-1}$ by applying the function $\text{Int}_i$ to each of its elements and by construction of $\text{Int}_i$, $\mathcal{I} \subseteq \text{Int}_i(\mathcal{I})$ and $\text{Int}_i(\mathcal{I}) \setminus \mathcal{I}$ does not contain any atoms on predicates from $S \cup \{\text{DbDom}, \text{First}, \text{Last}, \text{LT}, \text{Eq}, \text{NEq}\} \cup \{\text{In}_p, \text{NIn}_p | p \in S\}$. Hence the one-to-one correspondence between elements of $\mathcal{I}_i$ and pairs of the form $(\bar{T}, \mathcal{F}_D)$ is preserved when applying $\text{Int}_i$ to elements of $\mathcal{I}_{i-1}$ to obtain the elements of $\mathcal{I}_i$ for each $2 \leq i \leq 5$.

**Lemma 5.** $\mathcal{I}_1 = \bigcup_{\mathcal{I} \in \text{Ords}} \text{Compls}(\bar{T})$ is a universal model set of $\mathcal{R}_1$ and $\mathcal{D}$.

**Proof.** Let $\mathcal{K}$ be the result of some chase tree for $\mathcal{R}_1$ and $\mathcal{D}$ that prioritises the application of rules in the order of their appearance in Figure 1. By Fact 2, $\mathcal{K}$ is a universal model set for $\mathcal{R}_1$ and $\mathcal{D}$ and we show that each $\mathcal{K} \in \mathcal{K}$ is isomorphic to a unique $\mathcal{I} \in \mathcal{I}_1$.

We use the one-to-one correspondence between the interpretations in $\mathcal{I}_1$ and the pairs of the form $(\bar{T}, \mathcal{F}_D)$ described in Lemma 26. Since $\mathcal{K}$ is a result of the chase on $\mathcal{R}_1$ and $\mathcal{D}$, the domain of every $\mathcal{K} \in \mathcal{K}$ contains all nulls in $\text{Nulls}(\mathcal{D})$ and exactly two fresh nulls introduced to satisfy rules (2) and (3),
respectively. We name them $u_\alpha$ and $u_\omega$ respectively, so that $\Delta$ is the domain of $K$, and define a one-to-one correspondence between the interpretations in $\mathfrak{I}$ and the pairs of the form $(\vec{T}, \mathcal{F}_D)$ as in Lemma 26. This can be done because of the following points:

- Every $K \in \mathfrak{I}$ includes $D$ and does not contain any other atom on predicates from $\mathcal{S}$ because such predicates do not occur in rule heads.
- Every $K \in \mathfrak{I}$ includes $\{\text{DbDom}(t) \mid t \in \Delta\}$ and does not contain any other atom on predicate $\text{DbDom}$ (since there are no more nulls).
- Every $K \in \mathfrak{I}$ includes a $D$-order corresponding to some $\vec{T} \in \text{Ords}$ and does not contain any other atom on predicates from $\{\text{First}, \text{Last}, \text{LT}, \text{Eq}, \text{NEq}\}$:
  
  \begin{itemize}
  
  \item Let $\sim$ be the relation over $\Delta$ defined by $t \sim t'$ iff $\text{Eq}(t, t') \in K$. This is an equivalence relation because (i) $\{\text{DbDom}(t) \mid t \in \Delta\} \subseteq K$ and $K$ satisfies (5) (reflexivity); (ii) $K$ satisfies (6) (symmetry); and (iii) $K$ satisfies (8) instantiated for $R = \text{Eq}$ (transitivity). The equivalence classes form a partition $T_1, \ldots, T_k$ of $\Delta$ such that $\{\text{Eq}(t, u) \mid 1 \leq i \leq k; t, u \in T_i\} \subseteq K$.
  
  \item For every $u, t \in \Delta$, $K$ contains at least one of $\{\text{Eq}(u, t), \text{NEq}(u, t)\}$ because it satisfies (9). Moreover, $K$ cannot contain both $\text{Eq}(u, t)$ and $\text{NEq}(u, t)$ because the rules (5), (6) and (8) have a higher priority than (9). Hence $\{\text{NEq}(u, t), \text{NEq}(u, t)\} \ {1 \leq i < j \leq k; t, u \in T_i \setminus T_j} \subseteq K$.
  
  \item $K$ includes $\{\text{First}(u) \mid u \sim u_\alpha\}$ and $\{\text{Last}(u) \mid u \sim u_\omega\}$ by definition of $u_\alpha, u_\omega$ and because it satisfies (8). Assuming w.l.o.g. that $T_1$ is the equivalence class of $u_\alpha$ and $T_k$ that of $u_\omega$: $\{\text{First}(t) \mid t \in T_1\} \cup \{\text{Last}(t) \mid t \in T_k\} \subseteq K$.
  
  \item $K$ does not include any other atom over $\text{First}$ or $\text{Last}$ because rules (2) and (3) are applied only once.
  
  \item For every $u, t \in \Delta$ such that $\text{NEq}(u, t) \in K$, $K$ contains at least one of $\{\text{LT}(u, t), \text{LT}(t, u)\}$ because it satisfies (13).
  
  \item For every $u, t \in \Delta$, if $\text{First}(u) \in K$ (i.e. $u \sim u_\alpha$) and $\text{First}(t) \notin K$ (i.e. $t \not\sim u_\alpha$) then $\text{LT}(u, t) \in K$ because of (11).
  
  \item For every $u, t \in \Delta$, if $\text{Last}(u) \in K$ (i.e. $u \sim u_\omega$) and $\text{Last}(t) \notin K$ (i.e. $t \not\sim u_\omega$) then $\text{LT}(t, u) \in K$ because of (12).
  
  \item If $\text{LT}(u, t) \in K$ then $\text{LT}(u', t') \in K$ for all $u' \sim u$ and $t \sim t'$ because $K$ satisfies (8).
  
  \item $K$ contains the transitive closure of $\text{LT}$ because it satisfies (10).
  
  \item Since the rules (11), (12), (5), (6), (8), and (10) have a higher priority than (13), then $K$ cannot contain both $\text{LT}(u, t)$ and $\text{LT}(t, u)$.
  
  \item Hence $T_1, \ldots, T_k$ can be ordered in a way such that $\{\text{LT}(t, u) \mid 1 \leq i < j \leq k; t, u \in T_i \} \subseteq K$ and the ordered partition corresponds to some $\vec{T} \in \text{Ords}$ as required.
  
  \item Every $K \in \mathfrak{I}$ contains a complete $D$-completion $\mathcal{F}_D$ and does not contain any other atom on predicates from $\{\text{In}_p, \text{NI}_p \mid p \in S\}$:
  
  \begin{itemize}
  
  \item $K$ includes $\{\text{In}_p(\vec{t}) \mid p(\vec{t}) \in D\}$ because it satisfies (4).
  
  \item For every $p \in S$ and tuple $\vec{t} \subseteq \Delta$ of matching arity, $K$ contains at least one of $\{\text{In}_p(\vec{t}), \text{NI}_p(\vec{t})\}$ because it satisfies (14). We know that it does not contain both. The rules of the form (14) have the lowest priority and applying such a rule can only trigger the application of some rules of the form (8), which themselves cannot trigger the application of any rules but (8). Hence, (i) the application of these rules in the chase tree happens after the construction of the $D$-order in $K$, and (ii) when a rule of the form (14) is applied and adds some $\text{In}_p(\vec{t})$ (resp. $\text{NI}_p(\vec{t})$), the exhaustive application of rules (8) adds all $\text{In}_p(\vec{t})$ (resp. $\text{NI}_p(\vec{t})$) such that $\vec{t} \sim \vec{t}',$ where $\vec{t} \sim \vec{t}'$ iff $t_i \sim t_i'$ for every $i$. Suppose for a contradiction that there exists $\vec{u}$ such that $\text{In}_p(\vec{u}) \in K$ and $\text{NI}_p(\vec{u}) \in K$. Since the rules (14) and (8) are the only ones that have predicates from $\{\text{In}_p, \text{NI}_p \mid p \in S\}$ in the head, it follows that there exist $\text{In}_p(\vec{u}_1) \in K$ and $\text{NI}_p(\vec{u}_2) \in K$ that have both been added by some application of (14) and are
such that \( \vec{u}_1 \sim \vec{u} \) and \( \vec{u}_2 \sim \vec{u} \). Assume that \( \text{Inp}(\vec{u}_1) \) was added first. Then by (ii) \( \text{Inp}(\vec{u}_2) \) has been added before any new application of (14), and the rule \( \bigwedge_{x \in \vec{x}} \text{DbDom}(x) \to \text{Inp}(\vec{x}) \lor \text{NInp}(\vec{x}) \) with the substitution that maps \( \vec{x} \) to \( \vec{u}_2 \) was already satisfied, contradicting the introduction of \( \text{NInp}(\vec{u}_2) \).

- For every \((\vec{T}, \mathcal{F}_D)\), there exists \( K \in \mathcal{R} \) that corresponds to \((\vec{T}, \mathcal{F}_D)\). The existence of \( K \) is witnessed by the path of the chase tree such that for every vertex labelled with \( E \) where a disjunctive rule (9), (13), or (14) is applied, the path chooses the child labelled with \( C_i = E \cup \sigma_i(\eta_i) \) where \( \sigma_i(\eta_i) \) is included in \( \mathcal{F}_D \) or in the \( D \)-order corresponding to \( \vec{T} \).

Hence, we can define a one-to-one correspondence between interpretations in \( \mathcal{R} \) and interpretations in \( \mathcal{J}_1 \), using the corresponding pairs of the form \((\vec{T}, \mathcal{F}_D)\). By construction, every \( K \in \mathcal{R} \) and \( \mathcal{I} \in \mathcal{J}_1 \) that are in correspondence are isomorphic (note that since we choose to name the two fresh nulls \( u_\alpha \) and \( u_\omega \), they are actually identical).

**Lemma 27.** Given some \( \mathcal{I} \in \mathcal{J}_1 \), \( \text{Int}_2(\mathcal{I}) \) is isomorphic to the unique interpretation in a result of the chase over \( \mathcal{R}_2 \) and \( \mathcal{I} \).

**Proof.** We will let \( \text{Order}(\mathcal{F}) = T_1, \ldots, T_k \). The interpretation \( \text{Int}_2(\mathcal{I}) \) is equal to:

\[
\mathcal{I} \cup \{ \text{Root}(u_1) \} \cup \{ \text{Chi}(u_w, u_{w_2}) \mid wz \in \mathbb{Z}, 2 \leq z \leq k \} \cup \\
\{ \text{Leaf}(u_w) \mid w \in \mathbb{Z}, \text{end}(w) = k \} \cup \{ \text{Rep}(x, u_w) \mid w \in \mathbb{Z}; x \in T_{\text{end}(w)} \} \cup \\
\{ \text{Inp}(u_{w_1}, \ldots, u_{w_{\text{Ar}(p)}}) \mid \text{Inp}(t_1, \ldots, t_{\text{Ar}(p)}) \in \mathcal{I}; w_1 \in \mathbb{Z}; t_1 \in T_{\text{end}(w_1)}; 1 \leq i \leq \text{Ar}(p) \} \cup \\
\{ \text{NInp}(u_{w_1}, \ldots, u_{w_{\text{Ar}(p)}}) \mid \text{NInp}(t_1, \ldots, t_{\text{Ar}(p)}) \in \mathcal{I}; w_1 \in \mathbb{Z}; t_1 \in T_{\text{end}(w_1)}; 1 \leq i \leq \text{Ar}(p) \}.
\]

We describe a chase over \( \mathcal{R}_2 \) and \( \mathcal{I} \) that prioritises rule (18) step by step (note that if we do not prioritise (18), we could get a result which is not isomorphic to \( \text{Int}_2(\mathcal{I}) \)). Instead of constructing an isomorphism by giving for each fresh null introduced during the chase its counterpart in \( \text{Int}_2(\mathcal{I}) \), we directly set the the names of the fresh nulls so that the chase result coincides with \( \text{Int}_2(\mathcal{I}) \). Note that no rule in Figure 1 is applicable to \( \mathcal{I} \) and that applying a rule in Figure 2 cannot make a rule in Figure 1 applicable.

- Apply \((\rho, \sigma)\) with \( \rho = (15) \) and \( \sigma \) the substitution that maps \( x \) to some \( t \in T_1 \) (recall that \( \{ \text{First}(t) \mid t \in T_1 \} \subseteq \mathcal{I} \)). This introduces a fresh null that we call \( u_{11} \), and adds \( \text{Root}(u_{11}) \) and \( \text{Rep}(t, u_{11}) \).
- Apply exhaustively (18): add \( \text{Rep}(t, u_{11}) \) for all \( t \in T_1 \).
- For \( 2 \leq i \leq k \):
  - Choose one \( t_1 \in T_1 \) and one \( t_i \in T_i \) and apply \((\rho, \sigma)\) with \( \rho = (16) \) and \( \sigma \) the substitution that maps \( x \) to \( t_1 \), \( v \) to \( u_{11} \), and \( z \) to \( t_i \) (recall that the atoms on predicate \( LT \) in \( \mathcal{I} \) are \( \{ LT(t, u) \mid 1 \leq j < j' \leq k, t \in T_j, u \in T_{j'} \} \)). This introduces a fresh null that we call \( u_{1i} \), and adds \( \text{Chi}(u_{11}, u_{1i}), \text{Rep}(t_i, u_{1i}) \) (note that this is the first fact of the form \( \text{Rep}(t_i, x) \) with \( t_i \in T_1 \) that we introduce).
  - Apply exhaustively (18): add \( \text{Rep}(t_i, u_{1i}) \) for all \( t_i \in T_1 \).
- Continue applying (16) and (18) exhaustively as done in the previous step, introducing all nulls of the form \( u_{w_1} \) with \( w \in \mathbb{Z} \), and adding facts \( \{ \text{Chi}(u_{w_1}, u_{w_2}) \mid wz \in \mathbb{Z}, 2 \leq z \leq k \} \) and \( \{ \text{Rep}(x, u_w) \mid w \in \mathbb{Z}; x \in T_{\text{end}(w)} \} \).
- Apply exhaustively (17) and add \( \{ \text{Leaf}(u_w) \mid w \in \mathbb{Z}; \text{end}(w) = k \} \) (recall that \( \{ \text{Last}(t) \mid t \in T_k \} \subseteq \mathcal{I} \)).
- Apply exhaustively (19): for all \( \text{Inp}(t_1, \ldots, t_{\text{Ar}(p)}) \in \mathcal{I} \), add all \( \text{Inp}(u_{w_1}, \ldots, u_{w_{\text{Ar}(p)}}) \) where \( t_i \in T_{\text{end}(w_i)} \).
- Apply exhaustively (20): for all \( \text{NInp}(t_1, \ldots, t_{\text{Ar}(p)}) \in \mathcal{I} \), add all \( \text{NInp}(u_{w_1}, \ldots, u_{w_{\text{Ar}(p)}}) \) where \( t_i \in T_{\text{end}(w_i)} \).
Lemma 6. \( \xi_2 = \{ \text{Int}_2(\mathcal{I}) \mid \mathcal{I} \in \xi_1 \} \) is a universal model set of \( \mathcal{R}_2 \) and \( \mathcal{D} \).

Proof. By Lemmas 5 and 27, \( \xi_2 \) only contains models of \( \mathcal{R}_2 \) and \( \mathcal{D} \). We show that for every model \( M \) of \( \mathcal{R}_2 \) and \( \mathcal{D} \), there exists \( I_2 \in \xi_2 \) and a homomorphism \( h_2 : I_2 \rightarrow M \).

1. Let \( M \) be a model of \( \mathcal{R}_2 \) and \( \mathcal{D} \).
2. By Lemma 5: since \( M \) is a model of \( \mathcal{R}_2 \supseteq \mathcal{R}_1 \) and \( \mathcal{D} \), there exist \( I_1 \in \xi_1 \) and a homomorphism \( h_1 : I_1 \rightarrow M \).
3. By Lemma 27: since \( I_1 \in \xi_1 \), there exists a chase over \( \mathcal{R}_2 \) and \( I_1 \) such that the unique interpretation \( J \) in its result is such that there exists an isomorphism \( g_2 : \text{Int}_2(\mathcal{I}_1) \rightarrow J \).
4. By definition of \( J \), and since no rule from \( \mathcal{R}_1 \) is applied in the chase of over \( \mathcal{R}_2 \) and \( I_1 \) (see proof of Lemma 27) and \( \mathcal{R}_2 \setminus \mathcal{R}_1 \) contains no disjunctive rules, it follows that \( J \) is a universal model of \( \mathcal{R}_2 \setminus \mathcal{R}_1 \) and \( I_1 \).
5. By (1), (2) and (4), there exists a homomorphism \( g_1 : J \rightarrow M \) that extends \( h_1 \).
6. Let \( I_2 = \text{Int}_2(\mathcal{I}_1) \in \xi_2 \). By (3) and (5), there is an homomorphism \( h_2 = g_2 \circ g_1 : I_2 \rightarrow M \).

In the next proofs, we will use the following notation. Given a chase tree node labelled \( C_i = E \cup \sigma_i(\eta_i) \) and obtained by applying some \( (\rho, \sigma) \) to its parent node labelled by \( E \), then for each variable \( y \) of \( \rho \) not in the domain of \( \sigma \), we denote by \( u_{\sigma,\rho,y} \) the fresh null such that \( \sigma_i(y) = u_{\sigma,\rho,y} \) where \( \sigma_i \) is as introduced in Definition 2.

Lemma 28. Given some \( \mathcal{I} \in \xi_2, \) \( \text{Int}_3(\mathcal{I}) \) is well-defined and \( \text{Int}_3(\mathcal{I}) \) is isomorphic to the unique interpretation in a result of the chase over \( \mathcal{R}_3 \) and \( \mathcal{I} \).

Proof. We will let \( \text{Order}(\mathcal{I}) = T_1, \ldots, T_k \). The interpretation \( \text{Int}_3(\mathcal{I}) \) is equal to the union of the following databases:

1. \( \mathcal{I} \).
2. For each \( w \in \mathcal{Z} \) of length \( |w| \), with \( b_1 \cdots b_{|w|} \) the binary representation of \( |w| + 1 \), the database \( \text{EncPos}(w) \):
   \[
   \{ \text{Enc}(u_w, e_w^1, e_w^2) \} \cup \{ S_b_i(e_w^i) \mid 1 \leq i \leq \ell \} \cup \{ \text{Nxt}(e_w^{i-1}, e_w^i) \mid 2 \leq i \leq \ell \}.
   \]
3. For each \( w \in \mathcal{Z} \) of length \( |w| < k \), and \( z \in \{1, \ldots, k\} \) such that \( wz \in \mathcal{Z} \), with \( b_1 \cdots b_{|w|} \) the binary representation of \( |w| + 2 \) and \( b'_1 \cdots b'_{|w|} \) the binary representation of \( |w| + 1 \), the database \( \text{CpyPlusOne}(w, wz) \) defined as follows:
   \[
   \{ \text{Cpy}_{z+1}(e_w^1, e_w^2, e_w^i, e_w^j) \mid \text{the number represented by } b_1 \cdots b_{|w|} \text{ is equal to the number represented by } b'_1 \cdots b'_{|w|} \text{ plus one} \}
   \]
   \[
   \cup \{ \text{Cpy}(e_w^1, e_w^2, e_w^i, e_w^j) \mid b_1 \cdots b_{|w|} = b'_1 \cdots b'_{|w|} \}.
   \]

We describe a (Datalog-first) chase over \( \mathcal{R}_3 \) and \( \mathcal{I} \) step by step. We directly set the the names of the fresh nulls so that the chase result coincides with \( \text{Int}_3(\mathcal{I}) \). Note that no rule in Figures 1 or 2 is applicable to \( \mathcal{I} \) and that applying a rule in Figure 3 cannot make a rule in Figures 1 or 2 applicable.

- Apply \( (\rho, \sigma) \) with \( \rho = (21) \) and \( \sigma(u) = e_1^2 \). This introduces two fresh nulls, \( u_{\sigma,\rho,y_1} = e_1^2 \) and \( u_{\sigma,\rho,y_2} = e_1^2 \) and adds \( \text{Enc}(u_1, e_1^1, e_1^2), \text{S}_0(e_1^1), \text{Nxt}(e_1^1, e_1^2) \) and \( \text{S}_1(e_1^2) \).

We show by induction on \( p \) that for every \( w \in \mathcal{Z} \) of length \( |w| = p \) and \( z \in \{1, \ldots, k\} \) such that \( wz \in \mathcal{Z} \), our chase sequence adds \( \text{EncPos}(wz) \), and \( \text{CpyPlusOne}(w, wz) \).

Case \( p = 1 \). In this case, \( w = 1 \) and \( z \in \{2, \ldots, k\} \).

- For \( 2 \leq i \leq k \)
Proof. Similar to the proof of Lemma 6, using Lemmas 6 and 28.

Lemma 7. $\mathcal{I}_3 = \{ \text{Int}_3(I) \mid I \in \mathcal{I}_2 \}$ is a universal model set of $\mathcal{R}_3$ and $\mathcal{D}$.

Proof. Similar to the proof of Lemma 6, using Lemmas 6 and 28.
Lemma 29. Given some $I \in J_3$, $Int_3(I)$ is well-defined and $Int_4(I)$ is isomorphic to the unique interpretation in a result of the chase over $R_4$ and $I$.

Proof. Before giving the extension of $Int_4(I)$, we introduce some notation. Consider some fact of the form $\text{Leaf}(u_w) \in I$ and let $S = \text{branchTape}(I, u_w)$. By construction, $S = e_1 \cdots e_{|\text{branchDb}(I, u_w)|}$ where each $e_i$ corresponds to the serialisation of some $p^g_{\sigma}(u_{w_1}, \ldots, u_{w_x}) \in \text{branchDb}(I, u_w)$ and is of the form $p^g_{\sigma} \| [b^1_1 \cdots b^1_{\ell_1}] \cdots [b^\ell_t \cdots b^\ell_t_{\ell_t}]$ where $b^i_1 \cdots b^i_{\ell_i}$ is the binary representation of $|w_i| + 1$. For every $p^g_{\sigma} \in S$ and $u_{w_1}, \ldots, u_{w_x} \subseteq \text{branch}(u_w)$, let $j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x})$ and $j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x}) - 1$ be the indexes where the serialisation of $p^g_{\sigma}(u_{w_1}, \ldots, u_{w_x})$ starts and ends respectively if $p^g_{\sigma}(u_{w_1}, \ldots, u_{w_x}) \in \text{branchDb}(I, u_w)$, and otherwise $j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x}) = j^g_{\sigma}(p^{\sigma'}, u_{w_1}, \ldots, u_{w_x})$ be the index where the serialisation of the first fact of $\text{branchDb}(I, u_w)$ that follows $p^g_{\sigma}(u_{w_1}, \ldots, u_{w_x})$ according to $\prec$ (and $|S| + 1$ if there is no such fact). (Recall that $\prec$ is defined before Lemma 8.) It is easy to verify that:

- $j^g_{\sigma}(p^1_{\sigma}, u_w) = 1$.
- If $\text{In}^g_{p^g_{\sigma}}(u_{w_1}, \ldots, u_{w_x}) \notin I$, then $j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x}) = j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x})$.
- If $\text{In}^g_{p^g_{\sigma}}(u_{w_1}, \ldots, u_{w_x}) \in I$, then $j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x}) = j^g_{\sigma}(p^{g'}, u_{w_1}, \ldots, u_{w_x}) + \sum_{i=0}^{x} \ell_i + x + 2$, where $\ell_i$ is the length of the binary encoding of $|w_i| + 1$.
- If $g < \bar{n}$, then $j^g_{\sigma}(p^{g'}, u_{w_1}, \ldots, u_{w_x}) = j^g_{\sigma}(p^{g_{n+1}}, u_{w_1}, \ldots, u_{w_x})$.
- If $u_{w_1}, \ldots, u_{w_x} \neq u_1, \ldots, u_1$, then $j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x}) = j^g_{\sigma}(p^1_{\sigma}, u_{w_1}, \ldots, u_{w_x})$, where $u_{w_1}, \ldots, u_{w_x}$ comes right after $u_{w_1}, \ldots, u_{w_x}$ in the lexicographic order according to $\prec$.

Note that $j^g_{\sigma}(p^0_{\sigma}, u_1, \ldots, u_1) = |S| + 1$ and that for every $p^g_{\sigma}(u_{w_1}, \ldots, u_{w_x}) \in \text{branchDb}(I, u_w)$, if $b^1_1 \cdots b^\ell_{\ell_t}$ is the binary encoding of $|w_i| + 1 (1 \leq i \leq x)$, then:

- $S[j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x})] = p^g_{\sigma}$.
- $S[j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x}) + 1] = \|.$
- and for $1 \leq i \leq x$:
  - $S[j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x}) + i + \sum_{j=1}^{i-1} \ell_j + 1] = b^i_1$.
  - $\cdots$.
  - $S[j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x}) + i + \sum_{j=1}^{i-1} \ell_j + \ell_i] = b^\ell_i$.
  - $S[j^g_{\sigma}(p^g_{\sigma}, u_{w_1}, \ldots, u_{w_x}) + i + \sum_{j=1}^{i-1} \ell_j + 1] = \|.$

Finally, let $J_\sigma(u_w')$ be the set of indexes of $S$ where starts the sequence $\| b^1_1 \cdots b^\ell_{\ell_t} \|$ where $b^i_1 \cdots b^\ell_{\ell_t}$ is the binary representation of $|w'| + 1$. The interpretation $Int_4(I)$ is equal to the union of the following databases:

1. $I$;
2. For every $\text{Leaf}(u_w) \in I$ with serialisation $S = \text{branchTape}(I, u_w)$, the database startConf$(I, u_w)$:

\[
\{ \text{Ld}_1(u_w, t^1_{u_w}, u_w), \text{Hd}_{\sigma_S}(t^1_{u_w}), \text{End}(t^{|S|+1}_w), S_{\sigma_S}(t^{|S|+1}_w) \} \cup
\{ \text{Nxt}(t^{j-1}_{u_w}, t^j_{u_w}) | 2 \leq j \leq |S| + 1 \} \cup \{ S_a(t^j_{u_w}) | 1 \leq j \leq |S|, a = S[j] \}.
\]
3. For every Leaf\((u_w) \in \mathcal{I}\) with serialisation \(S = \text{branchTape}(\mathcal{I}, u_w)\), the database \(\text{loadS}(\mathcal{I}, u_w)\) defined as follows:

\[
\begin{align*}
\{ \text{Ld}_x(u_w, t^i_w, u_{w_1}, \ldots, u_{w_p}) \mid 1 \leq x \leq m; u_{w_i} \in \text{branch}(u_w); j = j^*_S(\rho^1_w, u_{w_1}, \ldots, u_{w_p}) \} \\
\cup \{ \text{Rdy}_x(u_w, t^i_w, u_{w_1}, \ldots, u_{w_p}) \mid 1 \leq x \leq m; u_{w_i} \in \text{branch}(u_w); j = j^*_S(\rho^2_w, u_{w_1}, \ldots, u_{w_p}) \} \\
\cup \{ \text{Ld}^p_g(u_w, t^i_w, u_{w_1}, \ldots, u_{w_p}) \mid 1 \leq g \leq \bar{n}; 1 \leq x \leq m; u_{w_i} \in \text{branch}(u_w); j = j^*_S(\rho^3_g, u_{w_1}, \ldots, u_{w_p}) \} \\
\cup \{ \text{Rdy}^p_g(u_w, t^i_w, u_{w_1}, \ldots, u_{w_p}) \mid 1 \leq g \leq \bar{n}; 1 \leq x \leq m; u_{w_i} \in \text{branch}(u_w); j = j^*_S(\rho^4_g, u_{w_1}, \ldots, u_{w_p}) \} \\
\cup \{ \text{LdE}(u_w^r, t^j_w + 1, t^j_w + 2) \mid u_{w_r} \in \text{branch}(u_w); b^l_1 \cdots b^l_{\bar{p}} \text{ bin. rep. of } |w^r| + 1; j \in J_S(u_w) \} \\
\cup \{ \text{Cpy}(e^w_r, e^w_{r+1}, t^j_w + 1) \mid u_{w_r} \in \text{branch}(u_w); b^l_1 \cdots b^l_{\bar{p}} \text{ bin. rep. of } |w^r| + 1; 1 \leq r \leq \ell - 1; j - 1 \in J_S(u_w) \}
\end{align*}
\]

We describe a (Datalog-first) chase over \(\mathcal{R}_4\) and \(\mathcal{I}\) step by step. We directly set the the names of the fresh nulls so that the chase result coincides with \(\text{Init}_4(\mathcal{I})\). Note that no rule in Figures 1, 2, or 3 is applicable to \(\mathcal{I}\) but that applying rule (30) may trigger the application of the "copy" rules (27) and (28) in Figure 3.

For every Leaf\((u_w) \in \mathcal{I}\) with serialisation \(S = \text{branchTape}(\mathcal{I}, u_w)\):

- Apply \(\langle \rho, \sigma \rangle\) with \(\rho = (31)\) and \(\sigma\) that maps \(u\) to \(u_w\). This introduces a fresh null that we call \(t^i_w\) and adds atoms \(\text{Ld}_1(u_w, t^i_w, u_{w_1})\) and \(\text{Rdy}^p_g(t^i_w)\). Note that \(j^*_S(\rho^1_w, u_w) = 1\) so that we have indeed added \(\text{Ld}_1(u_w, t^i_w, u_{w_1})\).

- Let \(\text{branch}(u_w) = \{ u_{w_1}, \ldots, u_{w_p} \}\) with \(u_w = u_{w_1} \prec \cdots \prec u_{w_p} = u_1\) (i.e. \(|w| = |w_1| > \cdots > |w_p| = 1\)). For \(1 \leq i \leq p\):
  - Apply (32) to \(\text{Ld}_1(u_w, t^i_w, j^*_S(\rho^1_w, u_{w_1}), u_{w_i})\) and add \(\text{Ld}^p_g(u_w, t^i_w, j^*_S(\rho^1_w, u_{w_1}), u_{w_i})\).

- For \(1 \leq g \leq \bar{n}\) and \(j = j^*_S(\rho^g, u_{w_i})\):
  - If \(\text{In}_g(u_{w_i}) \in \mathcal{I}\), apply (38) and add \(\text{Rdy}^p_g(u_w, t^i_w, j^*_S(\rho^1_w, u_{w_1}), u_{w_i})\). Note that \(j = j^*_S(\rho^1_w, u_{w_1}) = j^*_S(\rho^2_w, u_{w_1})\).
  - Else, \(\text{In}_g(u_{w_i}) \in \mathcal{I}\): apply \(\langle \rho, \sigma \rangle\) with \(\rho\) the instantiation of (29) for \(\rho^1_g\), and \(\sigma(u) = u_w\).

- If \(g < \bar{n}\): Apply (33) and add \(\text{Ld}^p_g(u_w, t^i_w, u_{w_i})\) with \(j' = j\) if \(\text{In}_g(u_{w_i}) \in \mathcal{I}\), \(j' = j + \ell_i + 3\) otherwise. Note that \(j' = j^*_S(\rho^1_w, u_{w_i}) = j^*_S(\rho^2_g, u_{w_i})\), independently of whether \(\text{In}_g(u_{w_i})\) is in \(\mathcal{I}\).

- Apply (34) and add \(\text{Rdy}_g(u_w, t^i_w, j^*_S(\rho^1_w, u_{w_i}))\).

- If \(i < p\) (i.e. \(u_{w_i} \neq u_1\)): Apply the instantiation of (35) \(\text{Rdy}_1(u, t, v) \land \text{Ch}(u, v) \rightarrow \text{Ld}_1(u, t, w)\) and add \(\text{Ld}_1(u_w, t^i_w, u_{w_{i+1}})\) with \(j' = j^*_S(\rho^1_w, u_{w_i}) = j^*_S(\rho^2_g, u_{w_{i+1}})\). Recall that \(u_{w_{i+1}}\) comes right after \(u_{w_i}\) in the lexicographic order according to \(\prec\).

- At the end of the above loop, we obtain an atom \(\text{Rdy}_1(u_w, t^i_w, j^*_S(\rho^1_w, u_{w_1}), u_1)\). Apply the instantiation of (36) \(\text{Rdy}_1(u, t, v) \land \text{Root}(v) \rightarrow \text{Ld}_2(u, t, u)\) and add \(\text{Ld}_2(u_w, t^i_w, j^*_S(\rho^1_w, u_{w_1}), u_{w_i})\). Note that \(j^*_S(\rho^1_w, u_1) = j^*_S(\rho^2_g, u_{w_1})\).

- Repeat the process, so that we obtain the atoms of the following form for \(2 \leq x \leq m\) and \(u_{w_1}, \ldots, u_{w_x} \in \text{branch}(u_w)\):
\begin{itemize}
  \item $\text{Ld}_k(u_w, t_{w}^j, u_w, \ldots, u_{w_j})$ where $j = j_S^*(p_{j}^i, u_w, \ldots, u_{w_j})$;
  \item $\text{Rdy}_k(u_w, t_{w}^j, u_w, \ldots, u_{w_j})$ where $j = j_S^*(p_{j}^i, u_w, \ldots, u_{w_j})$;
  \item for $1 \leq j \leq n$:
    \begin{itemize}
      \item $\text{Ld}_{p_j}^k(u_w, t_{w}^j, u_w, \ldots, u_{w_j})$ where $j = j_S^*(p_{j}^i, u_w, \ldots, u_{w_j})$;
      \item $\text{Rdy}_{p_j}^k(u_w, t_{w}^j, u_w, \ldots, u_{w_j})$ where $j = j_S^*(p_{j}^i, u_w, \ldots, u_{w_j})$;
    \end{itemize}
  \end{itemize}

* Apply exhaustively rules (27) and (28). This process introduces nulls – configuration \( \langle * \rangle \) for following atoms (cf. proof of Lemma 28):
* \( \text{S}_{p_j}^k(t_{w}^j) \)
  * \( \text{Nxt}(t_{w}^j, t_{w}^j+1) \), \( \text{Nxt}(t_{w}^j+\Sigma_{\ell=1}^i t_i+1, t_{w}^j+\Sigma_{\ell=1}^i t_i+2) \), \( \text{LdE}(u_{w_j}^j, t_{w}^j+1, t_{w}^j+\ell_i+2) \), \ldots, \( \text{LdE}(u_{w_j}^j, t_{w}^j+\Sigma_{\ell=1}^i t_i+1, t_{w}^j+\Sigma_{\ell=1}^i t_i+2) \)
* \( \text{S}_{p_j}^k(t_{w}^j) \)

We have obtained an atom $\text{Rdy}_{\bar{m}}(u_w, t_{w}^j, u_1, \ldots, u_1)$ with $j = j_S^*(\bar{m}, u_1, \ldots, u_1) = \lvert S \rvert + 1$. Apply (37) and add $S_\ell(t_{w}^j+1)$ and $\text{End}(t_{w}^j+1)$.

For all $u_w \in \text{branch}(u_w)$ and atoms of the form $\text{LdE}(u_w, t_{w}^j, t_{w}^j+\ell_i+2)$:
* Apply $\langle \rho, \sigma \rangle$ with $\rho = (30)$ and $\sigma(u) = u_w$, $\sigma(x_w) = t_{w}^j+1$, $\sigma(x_{w_{\ell}}) = t_{w}^j+\ell_i$, $\sigma(y_i) = e_{w}^{j_i}$ and $\sigma(y_j) = e_{w}^{j_j}$ where $b_1 \cdots b_i$ is the binary representation of $\lvert w_i \rvert + 1$. This introduces two fresh nulls $u_{\rho, \sigma, x_1} = t_{w}^j+2$ and $u_{\rho, \sigma, x_2} = t_{w}^j+\ell_i+1$ and adds the atoms: $S_{\ell}(t_{w}^j+1)$, $\text{Nxt}(t_{w}^j+1, t_{w}^j+2)$, $\text{Cpy}(e_{w}^{\ell_i+1}, e_{w}^{\ell_i+2}, t_{w}^j+\ell_i+1)$, $\text{Nxt}(t_{w}^j+\ell_i+1, t_{w}^j+\ell_i+2)$ and $S_{\ell}(t_{w}^j+\ell_i+2)$.
* Apply exhaustively rules (27) and (28). This process introduces nulls $t_{w}^j+3, \ldots, t_{w}^j+\ell_i$ and adds the following atoms (cf. proof of Lemma 28):
  * $S_{\ell_{j_{\bar{m}}}}(t_{w}^j+2), \ldots, S_{\ell_{j_{\bar{m}}}}(t_{w}^j+\ell_i)$
  * $\text{Nxt}(t_{w}^j+2, t_{w}^j+3), \ldots, \text{Nxt}(t_{w}^j+\ell_i, t_{w}^j+\ell_i+1)$
  * $\text{Cpy}(e_{w}^{\ell_i+1}, e_{w}^{\ell_i+2}, t_{w}^j+\ell_i+1), \ldots, \text{Cpy}(e_{w}^{\ell_i+1}, e_{w}^{\ell_i+2}, t_{w}^j+\ell_i+1)$.

At this point, for every null $u_w$ such that $\text{Leaf}(u_w) \in \mathcal{I}$, we have added $\text{startConf}({\mathcal{I}}, u_w)$ and $\text{loadS}({\mathcal{I}}, u_w)$ and no rule is applicable.

\begin{lemma}
$\mathcal{I}_4 = \{ \text{Int}_4(\mathcal{I}) \mid \mathcal{I} \in \mathcal{I}_3 \}$ is a universal model set of $\mathcal{R}_4$ and $\mathcal{D}$.
\end{lemma}

\begin{proof}
Similar to the proof of Lemma 7, using Lemmas 7 and 29.
\end{proof}

Before proving Lemma 9, we introduce some notation about TM runs. A configuration for a TM $M = \langle Q, \Gamma, \delta \rangle$ is a finite sequence $C = C_1, \ldots, C_k$ where $C_i = \{ q, a \}$ for some $i \leq k$, $q \in Q$, and $a \in \Gamma$, while for each $j \neq i$, $C_j = \{ a_j \}$ for some $a_j \in \Gamma$. The successor configuration of $C$ under $M$, denoted $M(C)$, is the configuration $C' = C_1', \ldots, C_k'$ satisfying, assuming $\delta(q, a) = (q', a', l)$,

$\begin{align*}
C_j' \cap \Gamma &= \begin{cases}
\{ a' \} & \text{if } j = i, \\
\emptyset & \text{if } j = k + 1,
\end{cases} \\
C_j' \cap \Gamma &= \emptyset.
\end{align*}$

while $C_j' \cap Q = \{ q' \}$ if $j = \max(i, 1)$, otherwise $\emptyset$. For a word $\bar{\gamma} = \gamma_1, \ldots, \gamma_k$, let $StConf(M, \bar{\gamma} \rangle$ denote the sequence $\{ q_1, \gamma_2 \}, \{ q_2, \gamma_3 \}, \ldots, \{ q_k, \gamma_\ell \}$. Let $\text{Comp}(M, \bar{\gamma} \rangle = C_1, C_2, \ldots$ be the (possibly finite) configuration sequence satisfying $C_1 = StConf(M, \bar{\gamma} \rangle$ as well as $C_{i+1} = M(C_i)$, whenever defined (otherwise – and only then – the sequence ends at $i$). Note that $M$ halts on $\bar{\gamma} \rangle$ if $\text{Comp}(M, \bar{\gamma} \rangle$ is finite, and accepts $\bar{\gamma} \rangle$ if the last configuration in $\text{Comp}(M, \bar{\gamma} \rangle$ features $q_A$.

\begin{lemma}
Given some $\mathcal{I} \in \mathcal{I}_4$, $\text{Int}_5(\mathcal{I})$ is isomorphic to the unique interpretation in a result of the chase over $\mathcal{R}_5$ and $\mathcal{I}$.
\end{lemma}

\begin{proof}
The interpretation $\text{Int}_5(\mathcal{I})$ is equal to the union of the following interpretations:
1. \( \mathcal{I} \):

2. For each \( w \in \mathbb{Z} \) with \( b_1 \cdots b_t \) the binary representation of \(|w| + 1\): \( \{ \text{Nxt}(e^i_w, e^j_w) \mid 1 \leq i < j \leq \ell \} \).

3. For each \( u_w \in \text{Nulls}(\mathcal{I}) \) with \( S = \text{branchTape}(\mathcal{I}, u_w) \), \( \text{Comp}(M, S) = \overline{C}_1, \ldots, \overline{C}_\ell \), and \( \overline{C}_i = C_{i,1}, \ldots, C_{i,|S|+1} \) for each \( 1 \leq i \leq \ell \), the database \( \text{Run}(u_w) \) defined as follows:

\[
\{ \text{Nxt}(t^{i,j}_w) \mid 1 \leq i < j \leq |S| + 1 \} \cup \\
\{ \text{End}(t^{i,j}_{w,i}) \mid 2 \leq i \leq \ell \} \cup \\
\{ \text{Nxt}(t^{i,j-1}_w, t^{i,j}_w) \mid 2 \leq i \leq \ell, 2 \leq j \leq |S| + i \} \cup \\
\{ \text{Nxt}(t^{i,j}_w, t^{i,j'}_w) \mid 1 \leq i \leq \ell, 1 \leq j < j' \leq |S| + i \} \cup \\
\{ \text{Step}(t^{i,j-1}_w, t^{i,j}_w) \mid 3 \leq i \leq \ell, 1 \leq j \leq |S| + i - 1 \} \cup \\
\{ \text{S_n}(t^{i,j}_w) \mid 2 \leq i \leq \ell, 1 \leq j \leq |S| + i, a \in C_{i,j} \} \cup \\
\{ \text{Hd}(t^{i,j}_w) \mid 2 \leq i \leq \ell, 1 \leq j \leq |S| + i, q, a \in C_{i,j} \} \cup \\
\{ \text{Goal} \mid 1 \leq j \leq |S| + \ell, q_A \in C_{i,j} \};
\]

We describe a (Datalog-first) chase over \( \mathcal{R}_a \) and \( \mathcal{I} \) step by step. We directly set the the names of the fresh nulls so that the chase result coincides with \( \text{Int}_a(\mathcal{I}) \). Note that no rule in Figures 1, 2, 3, 4, or 5 is applicable to \( \mathcal{I} \) and that applying a rule in Figure 6 cannot make a rule in Figures 1, 2, 3, 4, or 5 applicable.

We first apply exhaustively (40) and (41) which compute a transitive closure on the atoms of the form \( \text{Nxt}(e^i_w, e^j_w) \) and \( \text{Nxt}(t^{i,j}_w, t^{i,j}_w) \) in \( \mathcal{I} \). This adds the atoms \( \{ \text{Nxt}(e^i_w, e^j_w) \mid 1 \leq i < j \leq \ell \} \) described in point (2) and \( \{ \text{Nxt}(t^{i,j}_w, t^{i,j}_w) \mid 1 \leq i < j \leq |S| + 1 \} \) of the first line in point (3).

For every null \( u_w \) such that \( \text{Leaf}(u_w) \in \mathcal{I} \), \( S = \text{branchTape}(\mathcal{I}, u_w) \) and \( \text{Comp}(M, S) = \overline{C}_1, \ldots, \overline{C}_\ell \), we show by induction that for every \( 2 \leq i \leq \ell \) the following atoms belong to the chase result:

- \( \text{End}(t^{i,j}_w) \).
- \( \text{Nxt}(t^{i,j-1}_w, t^{i,j}_w) \) for \( 2 \leq j \leq |S| + i \).
- \( \text{Nxt}(t^{i,j}_w, t^{i,j'}_w) \) for \( 1 \leq j < j' \leq |S| + i, i \).
- \( \text{Step}(t^{i,j-1}_w, t^{i,j}_w) \) for \( 1 \leq j \leq |S| + i - 1 \).
- \( \text{S_n}(t^{i,j}_w) \) for \( 1 \leq j \leq |S| + i, a \in C_{i,j} \).
- \( \text{Hd}(t^{i,j}_w) \) for \( 1 \leq j \leq |S| + i, q, a \in C_{i,j} \).

**Base case** \( i = 2 \). Recall that for every \( \text{Leaf}(u_w) \in \mathcal{I} \) with serialisation \( S = \text{branchTape}(\mathcal{I}, u_w) \), \( \mathcal{I} \) includes:

\[
\{ \text{Ld}(u_w, t^1_w, u_w), \text{Hd}(t^1_w), \text{End}(t^1_w|S+1), S_n(t^1_w) \cup \{ \text{Nxt}(t^{1,j-1}_w, t^{1,j}_w) \mid 2 \leq j \leq |S| + 1 \} \cup \\
\{ S_n(t^1_w) \mid 1 \leq j \leq |S| + 1, a \in C_{j} \} \}.
\]

Moreover \( \overline{C}_1 = \text{StConf}(M, S) = \{ q_S, S[1] \}, \{ S[2] \}, \ldots, \{ S[|S|] \}; \} \). Let \( (q_S, S[1]) \mapsto (r, b, +1) \in \delta \) (recall that we assume that the TM will never attempt to move left on the first position of the tape). By definition, we have \( C_{2,1} \cap \Gamma = \{ b \}, C_{2,j} \cap \Gamma = C_{1,j} \cap \Gamma = \{ S[j] \} \) for every \( 1 < j \leq |S| + 1 \), and \( C_{2,2} \cap \Gamma = \{ r \} \).

- For every \( 1 < j \leq |S| + 1 \), let \( a \in C_{1,j} \cap \Gamma = C_{2,j} \cap \Gamma \).
  - Apply \( \langle \rho, \sigma \rangle \) with \( \rho \) the instantiation of (45) for transition \( (q_S, S[1]) \mapsto (r, b, +1) \) and tape symbol \( S[j] \), and \( \sigma(x) = t^2_w, \sigma(y) = t^3_w \). This introduces a fresh null \( u_{\rho, \sigma, z} = t^2_w \) and adds \( \text{Step}(t^2_w, t^3_w) \) and \( S_{S[j]}(t^2_w) \).
• Apply $\langle \rho, \sigma \rangle$ with $\rho$ the instantiation of (44) for $(q_S, S[1]) \mapsto (r, b, +X)$ and $\sigma(x) = t_w$. This introduces a fresh null $u_{\rho,\sigma,z} = t_{w}^{2,1}$ and adds $\text{Stp}(t_{w}^{2,1}, t_{w}^{2,1})$ and $\text{Stp}(t_{w}^{2,1})$.

• Apply $\langle \rho, \sigma \rangle$ with $\rho = (43)$ with $\sigma(x) = t_{w}^{j+1}$ and $\sigma(z) = t_{w}^{j+1}$. This introduces a fresh null $u_{\rho,\sigma,v} = t_{w}^{j+1} + 1$ and $\text{Nxt}(t_{w}^{j+1}, t_{w}^{j+1} + 1, t_{w}^{j+1} + 2, t_{w}^{j+1} + 2), S_u(t_{w}^{j+1} + 2)$ and $\text{End}(t_{w}^{j+1} + 2)$.

• Apply exhaustively (42), adding all atoms $\text{Nxt}(t_{w}^{j+1} - 1, t_{w}^{j+1})$ for $2 \leq j \leq |S| + 2$.

• Apply exhaustively (40) and (41), adding all atoms $\text{Nxt}^+(t_{w}^{j+1}, t_{w}^{j+1} + 1)$ for $1 \leq j < j' \leq |S| + 2$.

• Apply (47) and add $\text{Hd}_r(t_{w}^{2,2})$.

\textbf{Induction step:} Assume the property is true for some $2 \leq i < \ell$ and let $j_0$ be the unique $C_{i,j_0}$ such that $C_{i,j_0} \cap Q \neq \emptyset$, $\{q_0\} = C_{i,j_0} \cap Q$, $\{a_0\} = C_{i,j_0} \cap \Gamma$, and $(q_0, a_0) \mapsto (r, b, +X) \in \delta$. By definition, we have $C_{i+1,j_0} \cap \Gamma = \{b\}, C_{i+1,j} \cap \Gamma = C_{i,j} \cap \Gamma$ for every $j \neq j_0$, and $C_{i+1,j_0} \cap \Gamma = \{r\}$.

• For every $j > j_0$ (resp. $j < j_0$), let $a \in C_{i,j} \cap \Gamma = C_{i+1,j} \cap \Gamma$.

  • Apply $\langle \rho, \sigma \rangle$ with $\rho$ the instantiation of (45) (resp. (46)) for transition $(q_0, a_0) \mapsto (r, b, +X)$ and tape symbol $a$, and $\sigma(x) = t_w^{j_0}, \sigma(y) = t_w^{j_0}$. This introduces a fresh null $u_{\rho,\sigma,z} = t_w^{j_0}$ and adds $\text{Stp}(t_{w}^{j_0}, t_{w}^{j_0})$ and $\text{Stp}(t_{w}^{j_0}, t_{w}^{j_0})$.

  • Apply $\langle \rho, \sigma \rangle$ with $\rho = (43)$ with $\sigma(x) = t_w^{j_0}, \sigma(y) = t_w^{j_0}$. This introduces a fresh null $u_{\rho,\sigma,v} = t_w^{j_0} + 1$ and $\text{Nxt}(t_{w}^{j_0}, t_{w}^{j_0} + 1, t_{w}^{j_0} + 2, t_{w}^{j_0} + 2), S_u(t_{w}^{j_0} + 2)$ and $\text{End}(t_{w}^{j_0} + 2)$.

  • Apply exhaustively (42), adding all atoms $\text{Nxt}(t_{w}^{j_0} + 1, t_{w}^{j_0} + 1)$ for $2 \leq j \leq |S| + 2 + 1$.

  • Apply exhaustively (40) and (41), adding all atoms $\text{Nxt}^+(t_{w}^{j_0} + 1, t_{w}^{j_0} + 1)$ for $1 \leq j < j' \leq |S| + 2 + 1$.

  • If $X = +1$, apply (47) and add $\text{Hd}_r(t_{w}^{j_0} + 1, X)$.

  • If $X = -1$, then $j_0 > 1$ (since the TM never attempts to move left on the first position of the tape): apply (48) and add $\text{Hd}_r(t_{w}^{j_0} + 1, X)$.

We have shown that all atoms of $\text{Run}(u_w)$ but $\text{Goal}$ belong to the chase result. Finally, for every null $u_w$ such that $\text{Leaf}(u_w) \in \mathcal{I}$, $S = \text{branchTape}(\mathcal{I}, u_w)$ and $\text{Comp}(M, S) = \bar{C}_1, \ldots, \bar{C}_\ell$, if there exists $j$ such that $\text{Hd}_{\rho}(t_{w}^{j'}) \in \text{Run}(u_w)$, apply (39) and add $\text{Goal}$.

**Lemma 9.** $\mathcal{I}_5 = \{ \text{Int}_5(\mathcal{I}) \mid \mathcal{I} \in \mathcal{I}_4 \}$ is a universal model set of $\mathcal{R}_5$ and $\mathcal{D}$.

**Proof.** Similar to the proof of Lemma 8, using Lemmas 8 and 30.

**Lemma 10.** If $\mathcal{D} \in \mathcal{Q}$, then $\text{Goal} \in \mathcal{I}$ for each $\mathcal{I} \in \mathcal{M}$.

**Proof.** Let $\mathcal{I} \in \mathcal{M}$. We have shown that there is a homomorphism $\mathcal{D} \rightarrow \text{branchDb}(\mathcal{I}, u_w)$ for the node $u_w$ where $|w| = |\text{Order}(\mathcal{I})|$. Since $\mathcal{Q}$ is closed under homomorphisms, $\mathcal{D} \in \mathcal{Q}$ implies $\text{branchDb}(\mathcal{I}, u_w) \in \mathcal{Q}$.

Let $\text{Comp}(M, S) = \bar{C}_1, \ldots, \bar{C}_\ell$ be the computation of $M$ on the serialisation $S = \text{branchTape}(\mathcal{I}, u_w)$ of the database $\text{branchDb}(\mathcal{I}, u_w)$. Since $\text{branchDb}(\mathcal{I}, u_w) \in \mathcal{Q}$ and $M$ decides $\mathcal{Q}$, $\bar{C}_1, \ldots, \bar{C}_\ell$ is such that $\bar{C}_\ell$ features $\text{Goal}$. By construction of $\text{Run}(u_w)$ (see proof of Lemma 30), it follows that $\text{Goal} \in \text{Run}(u_w)$. Hence $\text{Goal} \in \mathcal{I}$.

**Lemma 11.** If $\mathcal{D} \notin \mathcal{Q}$, then $\text{Goal} \notin \mathcal{I}$ for some $\mathcal{I} \in \mathcal{M}$.
Proof. Consider some $\mathcal{I} \in \mathcal{M}$ such that $\text{Db}(\mathcal{I}) = \mathcal{D}$ and $\text{NEq}(t, u) \in \mathcal{I}$ for each $t, u \in \text{Nulls}(\mathcal{D})$ with $t \neq u$ (such a $\mathcal{I}$ exists by Lemma 26). Let $u_w$ denote the leaf node with $|w| = |\text{Order}(\mathcal{I})|$. Then $\text{branchDb}(\mathcal{I}, u_w)$ is isomorphic to $\text{Db}(\mathcal{I}) = \mathcal{D}$ and $\text{branchDb}(\mathcal{I}, u_w) \notin \Omega$.

Let $\text{Comp}(M, S) = C_1, \ldots, C_t$ be the computation of $M$ on the serialisation $S = \text{branchTape}(\mathcal{I}, u_w)$ of the database $\text{branchDb}(\mathcal{I}, u_w)$. Since $\text{branchDb}(\mathcal{I}, u_w) \notin \Omega$ and $M$ decides $\Omega$, $C_1, \ldots, C_t$ is such that $C_t$ does not feature $q_A$. By construction of $\text{Run}(u_w)$ (see proof of Lemma 30), it follows that $\text{Goal} \notin \text{Run}(u_w)$.

Moreover, for all other leaf nodes $u_v$ with $\text{Leaf}(u_v) \in \mathcal{I}$, there is a homomorphism $\text{branchDb}(\mathcal{I}, u_v) \rightarrow \text{branchDb}(\mathcal{I}, u_w)$. Since $\Omega$ is closed under homomorphisms, $M$ does not accept any such $\text{branchDb}(\mathcal{I}, u_v)$, and $\text{Goal} \notin \text{Run}(u_v)$. By construction of $\mathcal{M}$, $\text{Goal}$ occurs in $\mathcal{I}$ iff it occur in some $\text{Run}(u_v)$, so $\text{Goal} \notin \mathcal{I}$. □

B  Proofs for Section 5

We fix for this whole appendix part a split $(\Sigma_1, \Sigma_2)$ of $\Sigma$ fulfilling the condition of Item 2 of Lemma 18, and $\Sigma'_1, \Sigma'_2, \Sigma'_3$ built from $\Sigma_1, \Sigma_2$ as described in the body of the paper.

Proof of Proposition 19

Definition 6 (World Structure). Let $\mathcal{I}$ be an interpretation of $\Sigma'_1$. The world structure of $\mathcal{I}$ is the graph $(V, E)$ where:

- $V = \{w \mid \text{Done}(w) \in \mathcal{I}\}$
- $E = \{(w, w') \mid w \neq w' \land \exists \vec{x} \exists \vec{y} \text{ Ins}_p(\vec{x}, w, w') \in \mathcal{I}\}$

Lemma 31. For every $\mathcal{D}$ over $S_m(\Sigma)$, the world structure of a model $\mathcal{I}$ of $\mathcal{D}$ and $\Sigma'_1$ generated by a chase sequence is a finite tree, such that:

- its root is the unique element $w$ such that $\text{Empty}(w) \in \mathcal{I}$;
- if $(w, w') \in E$, then $\text{world}(w') = \text{world}(w) \cup \{p(\vec{x})\}$ for some atom $p(\vec{x})$, and $p(\vec{x}) \notin \text{world}(w)$;
- if $\text{Init}(w) \in \mathcal{I}$ and $p(\vec{a}) \in \mathcal{D} \setminus \text{world}(w)$, there exists $w'$ such that $\text{Ins}_p(\vec{a}, w, w') \in \mathcal{I}$.

Proof. Let us first notice that Rule (58) is applicable exactly once, as its frontier is empty. The null it creates, say $w_0$, is then the only one such that $\text{Empty}(w_0) \in \mathcal{I}$. Moreover, there is no edge incoming in $w_0$ in the world structure, as the only rules Rules (59), (60) and (61) that introduce an atom of the shape $\text{Ins}_p(\vec{a}, w, w')$ with $w \neq w'$ are such that $w'$ is existentially quantified. For the same reason, note that there is at most one edge incoming in any vertex in the world structure.

Next notice that no new null is created unless Rules (59), (60) or (61) are applied, and they all must be applied by mapping $w$ to an element of the world structure, as $\text{Done}(w)$ is in the body of each of these rules. Hence the world structure is connected, and is thus a tree of root $w_0$.

Now let us notice that in any interpretation $\mathcal{I}$ generated by a sequence of rule applications, if $\text{Done}(w) \in \mathcal{I}$, then $\text{world}(w) = \text{world}(w')$ for any $w'$ obtained by extending the sequence of rule applications that generated $\mathcal{I}$. Indeed, the only way to derive $\text{Done}(w)$ is to apply Rule (63), which requires the atoms $\text{Empty}(w_0)$ and $\text{Subs}(w_0, w)$, as $w_0$ is the only element for which $\text{Empty}$ holds. The only way to create an atom of the shape $\text{Subs}(w_0, w_2)$ with $w_0 \neq w_2$ is by applying an instantiation of Rule (62), which can be applied if $w_0$ is a parent of $w_1$ in the world structure, and $w_1$ is such that $\text{Subs}(w_1, w_2)$ holds. Hence $\text{Done}(w)$ is entailed only when Rule (62) has been applied by mapping $w_0$ to every ancestor of $w$ and $w_2$ to $w$, which has a effect to ensure that $\text{world}(w)$ contains all the atoms possibly present in $\text{world}(w'_1)$.

If $(w, w'_1) \in E$, then $w'_1$ has been created by the application of Rule (59), (60) or (61). In all cases, $\text{Done}(w)$ must hold at the time of the rule application. If it is by Rule (59) and substitution $\sigma$, then $p(\sigma(\vec{x}))$ cannot belong to $\text{world}(w)$, as this would make Rule (59) not applicable with $\sigma$. By the sequence of rule applications described before, $\text{world}(w') = \text{world}(w) \cup \{p(\sigma(\vec{x}))\}$. Rules (60) and (61) are treated in a similar way.
Both the depth and the arity of the world structure is thus upper bounded by the number of atoms using a predicate appearing in $\Sigma_1 \cup \Sigma_2$ and nulls from $D$.

For the last item, let us notice that if $\text{Init}(w) \in I$, and $p(\bar{a}) \in D \setminus \text{world}(w)$, then Rule (59) instantiated for $p$ is applicable by mapping $\bar{x}$ to $\bar{a}$. Applying that rule will create a fresh null $w'$ which will fulfill the conditions stated in the lemma. 

\begin{lemma}
Let $D$ be a database over $S_n(\Sigma)$, and let $I$ be a model of $D$ and $\Sigma_2'$ generated by a chase sequence. \text{Let } v \in \text{Nulls}(I) \text{ such that } \text{Done}(v) \in I. \text{ If a disjunctive rule } \rho \text{ is applicable to } \text{world}(v) \text{ by } \sigma, \text{ then there exist in } I \text{ two elements } w_1 \text{ and } w_2 \text{ such that } \text{Ins}_{p_1}(\bar{u}_1, v, w_1) \text{ and } \text{Ins}_{p_2}(\bar{u}_2, v, w_2) \text{ such that } p_1(\bar{u}_1) \text{ and } p_2(\bar{u}_2) \text{ are the two atoms created by the application of } \langle \rho, \sigma \rangle.
\end{lemma}

\begin{proof}
Let us first notice that $\sigma$, extended by mapping $w$ to $v$, is a substitution that maps the bodies of Rules (60) and (61) to $I$, by definition of $\text{world}(v)$ and since $\text{Done}(v) \in I$. As $I$ is a model of $\Sigma_1'$, the head of these two rules should be also mappable in $I$, hence there exists $w_1$ and $w_2$ fulfilling the conditions of the lemma.
\end{proof}

Note that Proposition 19 is a direct consequence of Lemmas 31 and 32.

\begin{proof}[Proof of Lemma 18]
\begin{definition}[Saturated World of a Null in an Interpretation]
Let $w$ be a null in an interpretation $\mathcal{I}$ such that $\text{Subs}(w, w) \in \mathcal{I}$. The saturated world of $w$ is defined by $\text{satWorld}_{\mathcal{I}}(w) = \{ p(\bar{x}) \mid p(\bar{x}, w) \in \mathcal{I} \}$.
\end{definition}

\begin{lemma}
If there is a chase tree w.r.t. $(\Sigma_1' \cup \Sigma_2')$ and $D$ whose unique leaf $I$ is such that there exists $w^* \in \text{Nulls}(I)$ s.t. $\text{Goal}_1 \in \text{satWorld}_{\mathcal{I}}(w^*)$ and $\text{Done}(w^*) \in I$, then there exists a chase tree w.r.t. $\Sigma_2$ and $\text{world}(w^*)$ whose unique leaf contains $\text{Goal}_1$.
\end{lemma}

\begin{proof}
Let us consider a chase tree $T'$ w.r.t. $(\Sigma_1' \cup \Sigma_2')$ and $D$, and let $w^*$ be such that $\text{Done}(w^*)$ is in the result $\mathcal{I}$ of $T'$. We show that there exists a chase tree $T$ w.r.t. $\Sigma_2$ and $\text{world}(w^*)$ such that $\text{satWorld}_{\mathcal{I}}(w^*)$ is mapped to the label of the (unique) leaf of $T$ by a homomorphism $\psi$.

For every label $J$ of a node in $T'$ such that $\text{Done}(w^*) \in J$, we show that there exists a prefix of a chase tree w.r.t. $\Sigma_2$ and $\text{world}(w^*)$ such that $\text{satWorld}_{\mathcal{I}}(w^*)$ is mapped to the label of the leaf of that prefix by a homomorphism $\psi$. We do this by induction on the number of rule applications $\langle \rho, h \rangle$ with $\rho$ of the form Rule (64) and $h(w) = w^*$ that are done in $T'$ before the node labelled by $J$.

- If no rule application of the shape $\langle \rho, h \rangle$ with $h(w) = w^*$ is performed in $T'$ before $J$, then $\text{satWorld}_{\mathcal{I}}(w^*) = \text{world}(w^*)$. We thus define $\psi$ as the identity, and the chase tree prefix consisting of the root labelled by $w^*$ fulfills the property.

- Assume that the property is true for every $J$ obtained in $T'$ after at most $i - 1$ applications of the shape $\langle \rho', h \rangle$ with $\rho'$ of the form Rule (64) and $h(w) = w^*$. Let $J'$ be obtained in $T'$ after $i$ such applications and let $\langle \rho', h \rangle$ be the last one, with $\rho'$ being the instantiation of Rule (64) for $\rho \in \Sigma_2$. Let $J_{i-1}$ be the label of the node in $T'$ on which $\langle \rho', h \rangle$ is applied. By induction assumption, there exist $\psi$ and a prefix of a chase tree for $\Sigma_2$ and $D$, resulting in $S_{i-1}$, such that $\psi(\text{satWorld}_{\mathcal{I}}(w^*)) \subseteq S_{i-1}$. Hence $\langle \rho, \psi \circ h_{\text{Terms}(B_\rho)} \rangle$, where $B_\rho$ is the body of $\rho$, is applicable on $S_{i-1}$, creating a new leaf, labeled by $S_i$, and we extend $\psi$ by mapping every null created by the instantiation of $z_i \in \mathcal{I}$ in the application of $\langle \rho', h \rangle$ to the null created by the instantiation of $z_i \in \mathcal{I}$ in the application of $\langle \rho, \psi \circ h_{\text{Terms}(B_\rho)} \rangle$. We obtain $\psi(\text{satWorld}_{\mathcal{I}}(w^*)) \subseteq S_i$. 

\end{proof}

\begin{lemma}
Any restricted chase w.r.t. $\Sigma_2' \cup \Sigma_2'' \cup \Sigma_3'$ can be transformed into an equivalent restricted chase in which rules from $\Sigma_1'$ are applied before rules from $\Sigma_2''$, which are applied before rules from $\Sigma_3$.
\end{lemma}
Proof. Notice that head predicates of \( \Sigma'_j \) do not appear in \( \{ \Sigma'_j \} \) with \( j < 3 \). Hence rules of \( \Sigma'_0 \) can be applied last. Note that head predicates of \( \Sigma'_3 \) do not appear as body predicates of \( \Sigma'_j \). Moreover, a rule of \( \Sigma'_2 \) is applicable by mapping \( w \) to \( w^* \) only if \( \text{Done}(w^*) \) has been derived. Further applications of rules of \( \Sigma'_2 \) cannot add an atom of the shape \( p'(\bar{x}, w^*) \), and thus applying them before do not prevent the application of a rule of \( \Sigma'_1 \).

\[ \Box \]

Proposition 35. For every database \( D \) over \( S_n(\Sigma) \), if \( \Sigma_1 \cup \Sigma_2 \models \text{Goal}_1 \) then \( \Sigma'_1 \cup \Sigma'_2 \cup \Sigma'_3 \cup \Sigma'_0 \cup \Sigma'_1 \cup \Sigma'_2 \cup \Sigma'_3 \models \text{Goal}_1 \).

Proof. Let us consider a finite chase tree \( T \) showing that \( \Sigma_1 \cup \Sigma_2 \models \text{Goal}_1 \) and that rules of \( \Sigma_1 \) are applied before rules of \( \Sigma_2 \) (this is possible by definition of \( \Sigma_1 \) and \( \Sigma_2 \) that form a split of \( \Sigma \)). We build a chase tree proving that \( \Sigma'_1 \cup \Sigma'_2 \cup \Sigma'_3 \cup \Sigma'_0 \cup \Sigma'_1 \cup \Sigma'_2 \cup \Sigma'_3 \models \text{Goal}_1 \) (we actually describe a sequence of rule applications, as \( \Sigma'_1 \cup \Sigma'_2 \cup \Sigma'_3 \cup \Sigma'_0 \cup \Sigma'_1 \cup \Sigma'_2 \cup \Sigma'_3 \) contains only deterministic rules).

1. Apply Rule (58), creating a fresh null \( w_0 \) and facts \( \text{Init}(w_0) \), \( \text{Done}(w_0) \) and \( \text{Empty}(w_0) \).
2. Until creation of \( w_D \), perform the following:
   - let \( w_D \) be the last introduced null;
   - let \( p(\bar{a}) \in D \setminus D' \);
     * apply Rule (59), instantiated for \( p \), by mapping \( \bar{x} \) to \( \bar{a} \) and \( w \) to \( w_D \), creating a fresh null \( w_{D' \cup \{p(\bar{a})\}} \);
     * apply Rule (62) as many times as necessary until Subs(\( w_0, w_{D' \cup \{p(\bar{a})\}} \)) is created, which makes Rule (63) become applicable by mapping \( w' \) to \( w_{D' \cup \{p(\bar{a})\}} \). Then apply Rule (63) and add \( \text{Done}(w_{D' \cup \{p(\bar{a})\}}) \).
3. At the end of the above loop, note that we have created null \( w_D \) and added in particular \( \text{Done}(w_D) \) as well as \( \text{Ins}_p(\bar{a}, w_D, w_D) \) and for every \( p(\bar{a}) \in D \).
4. Let \( r \) be the root node of \( T \). Note that \( r \) is labelled by \( D \). In what follows, we will introduce some nulls \( w_N \) such that \( N \) is the label of some node \( n \) in \( T \) and it will remain true that \( \text{Done}(w_N) \) as well as \( \text{Ins}_p(\bar{a}, w_N, w_N) \) for every \( p(\bar{a}) \in N \) are introduced between the creation of \( w_N \) and the creation of the next \( w_N \).
5. Define \( \psi(r) = w_D \) and let \( N = \{ r \} \) and \( L = \emptyset \). Until \( N = \emptyset \), perform the following.
   - Consider the case where \( n \) is a node of \( T \) labelled by \( N \) such that \( \psi(n) = w_N \) and \( n \) has two children \( c_1 \) and \( c_2 \) labelled by \( N_1 \) and \( N_2 \) respectively, which correspond to the application of \( \langle \rho, \sigma \rangle \) with \( \rho \in \Sigma_1 \) of the form \( \bigwedge_{p(\bar{x}) \in \rho} L(\bar{x}) \rightarrow p_1(\bar{x}_1) \lor p_2(\bar{x}_2) \). We have \( N_1 = \bigcup_{\mathcal{C}} \{ p_1(\bar{a}_1) \} \) and \( N_2 = N \setminus \{ p_2(\bar{a}_2) \} \) where \( \bar{a}_1 = \sigma(\bar{x}_1) \) and \( \bar{a}_2 = \sigma(\bar{x}_2) \). The instantiations of (60) and (61) corresponding to \( \rho \) are applicable through \( \sigma' \), which maps \( w \) to \( w_N \) and \( \bar{x} \) to \( \sigma(\bar{x}) \).
   * Apply Rule (60), introducing a fresh null that we call \( w_{N_1} \) and adding in particular \( \text{Ins}_p(\bar{a}_1, w_{N_1}, w_{N_1}) \). Then apply Rule (62) as many times as necessary, then Rule (63) so that \( \text{Done}(w_{N_1}) \) is created. Define \( \psi(c_1) = w_{N_1} \).
   * If Rule (61) is not applicable, it implies that \( p_1 = p_2 \) and \( \bar{a}_1 = \bar{a}_2 \), so that \( N_1 = N_2 \). Set \( N = (N \setminus \{ c_1 \} \} \setminus \{ n \} \), and set \( \psi(c_2) = w_{N_1} \).
   * Otherwise apply Rule (61), introducing a fresh null that we call \( w_{N_2} \) and adding in particular \( \text{Ins}_p(\bar{a}_2, w_{N_2}, w_{N_2}) \). Then apply Rule (62) as many times as necessary, then Rule (63) so that \( \text{Done}(w_{N_2}) \) is created. Define \( \psi(c_2) = w_{N_2} \) and set \( N = (N \setminus \{ c_1, c_2 \}) \setminus \{ n \} \).
   - If \( n \) is a node of \( T \) having only one child, set \( L = L \cup \{ n \} \) and set \( N = N \setminus \{ n \} \).

At this point, for every \( n \in L \), \( \psi(n) = w_N \) and if \( I \) denotes the current set of facts built by our derivation, \( \text{saturatedWorld}_I(\psi(n)) = N \) by construction.

For all \( n \in L \), the next rule applied on \( n \) is a rule from \( \Sigma_2 \), hence no more rule of \( \Sigma_1 \) are applied on a descendant of \( n \) in \( T \) (by assumption on \( T \)). All rule applications below \( n \) are thus deterministic, and we "copy" that derivation. Let \( \psi_n \) be the identity mapping from the label \( N \) of \( n \) to \( \text{saturatedWorld}_I(\psi(n)) \).
By construction, $\psi_n$ is a homomorphism. While we extend $I$ by applying new rules, we will extend $\psi_n$ into a homomorphism from the label of any descendant $n'$ of $n$ in $T$ to $\text{saturatedWorld}_I(\psi(n))$.

- For $n' = n$, this is already done.
- Assume that we have built a derivation such that $\psi_n$ is a homomorphism from the label $\mathcal{N}'$ of some descendant $n'$ of $n$ in $T$ to $\text{saturatedWorld}_I(\psi(n))$. Let $n''$ be the child of $n$ in $T$, labelled by $\mathcal{N}''$, and let $(\rho, \sigma)$ be the rule application creating $n''$, where $\rho \in \Sigma_2$. Then $(\rho, \psi_n \circ \sigma)$ can be applied to $\text{saturatedWorld}_I(\psi(n))$, and thus Rule (64), instantiated for $\rho$ is applicable in $I$ by extending $\psi_n \circ \sigma$ by mapping $w$ to $\psi(n)$. We then define $\psi(n'') = \psi(n)$, and extend $\psi_n$ by mapping each null created in the label of $n''$ by a variable $z_i$ to the null created by variable $z_i$ in the application of Rule (64).

Let $T'$ be the tree structure having $\psi(r) = w_D$ as root and where $w_p$ is parent of $w_c$ if $w_c$ has been created by an application of Rule (60) or Rule (61), that mapped $w$ to $w_p$. Note that all the $w_n$ in this tree structure are exactly the nulls of $I$ such that there exists a node $n$ in $T$ with $\psi(n) = w_n$, $c_1, c_2$ are children of $n$ in $T$ iff $\psi(c_1), \psi(c_2)$ are children of $\psi(n)$ in $T'$.

Let $\ell$ be a leaf of $T$. By assumption, $\text{Goal}$ belongs to the label of $\ell$. Let $n$ be the unique node in $L$ such that $\ell$ is a descendant of $n$. Since $\psi_n$ is a homomorphism from the label of $\ell$ to $\text{saturatedWorld}_I(\psi(n))$, it holds that $\text{saturatedWorld}_I(\psi(n))$ contains $\text{Goal}$. By definition of $\text{saturatedWorld}_I$, it follows that $\text{Goal}(\psi(n)) \in I$. Since any leaf $w_n$ of $T'$ has an antecedent $n$ by $\psi$ which has a descendant leaf $\ell$ in $T$, then $\text{Goal}(w)$ holds for each leaf $w$ of $T'$. Extend the derivation as follows:

- Apply Rule (65) to each $w$ leaf of $T'$.
- If $\text{Acc}(w)$ has already been derived for the children $w$ of a node $\psi(n)$ in $T'$, let $\rho$ be the rule that has been applied by $\sigma$ on $n$ to create its children. Apply Rule (66) instantiated for $\rho$ by mapping $w_1$ and $w_2$ to $\psi(c_1)$ and $\psi(c_2)$, where $c_1$ and $c_2$ are the children of $n$ corresponding to the application of $\rho$. $\text{Acc}(\psi(n))$ is thus derived.
- By induction on the depth, one derives $\text{Acc}(w_D)$. As $\text{Init}(w_D)$ holds, one can apply Rule (67) and obtain $\text{Goal}$.

We did not apply every possible rule: hence, to build a chase tree, we must ensure fairness (point 3. of the definition of chase tree), by applying all possible remaining rule applications, which concludes the proof.

To ease that proof, we will actually replace Rule (66) by the following rule:

$$
\begin{align*}
\text{Ins}_p(\vec{x}_1, w, w_1) & \land \text{Acc}(w_1) \land \\
\text{Ins}_p(\vec{x}_2, w, w_2) & \land \text{Acc}(w_2) \land \\
& \land_{\rho(\vec{x}) \in \beta} \text{Ins}_p(\vec{x}, w, w) \\
\end{align*}
\rightarrow \text{Acc}(w, w_1, w_2) \land \text{Acc}(w)
$$

which has an additional ternary fresh predicate describing the rule $\rho \in \Sigma_1$ (and the worlds generated by the corresponding rule application) allowing to derive $\text{Acc}(w)$. Note that since $\text{Acc}_p$ not being appearing anywhere else, all the properties shown so far are still valid.

**Proposition 36.** For every database $D$ over $\mathcal{S}_m(\Sigma)$, if $\Sigma_1 \cup \Sigma_2 \cup \Sigma_3$, $D \models \text{Goal}$ then $\Sigma_1 \cup \Sigma_2, D \models \text{Goal}$.

**Proof.** Let $I$ be a model of $D$ and $\Sigma_1 \cup \Sigma_2 \cup \Sigma_3$ obtained through a restricted chase sequence such that $\text{Goal} \in I$. We build a chase tree $T$ for $\Sigma_1 \cup \Sigma_2$ and $D'$ for some $D' \subseteq D$ such that $\text{Goal}$ is in the label of every leaf of $T$.

Let $w_{D'} \in \text{Nulls}(I)$ be such that Rule (67) is applied on it, with $\text{world}(w_{D'}) = D'$. Set $W = \{w_{D'}\}$, and perform the following until $W = \emptyset$.

- Let $w \in W$. If $\text{Goal}(w) \in I$, set $W = W \setminus \{w\}$.
• Otherwise, there must be some \( \text{Acc}_p(w, w_1, w_2) \in \mathcal{I} \), as the only way to derive \( \text{Acc}(w) \) if \( \text{Goal}^*(w) \) does not hold is to apply some instantiation for some \( p \) of Rule (68) by some mapping \( \sigma \). Moreover, there must be such an atom for which \( w_1 \) and \( w_2 \) are different from \( w \). Consider \( (\rho, \sigma_{\text{Term}(\rho)}) \): it is applicable, as \( \sigma \) maps the body of \( p \) to \( \text{world}(w) \), and none of the two atoms in the head are present in \( \text{world}(w) \) (otherwise, \( w \) would be equal to \( w_1 \) or to \( w_2 \)). Performing this rule application adds two children to the node of \( T \) labelled by \( \text{world}(w) \), of respective labels \( \text{world}(w_1) \) and \( \text{world}(w_2) \). Let

\[
W = (W \setminus w) \cup \{w_1, w_2\}.
\]

As the tree structure of \( \mathcal{I} \) is finite, and that at each step, either the size of \( W \) is decreasing, or the null \( w \) considered is replaced by two nulls \( w_1 \) and \( w_2 \) such that \( \text{world}(w_1) \) and \( \text{world}(w_2) \) are labels of nodes of strictly greater depth than \( \text{world}(w) \) in that tree, the above process terminates. Moreover, for each leaf of the considered prefix of \( T \), it holds that its label and \( \Sigma \) entail \( \text{Goal} \), by Lemma 33 and the fact that each leaf is labelled by some \( \text{world}(w) \) such that \( \text{Goal}^*(w) \in \mathcal{I} \) (so that \( \text{Goal} \in \text{saturatedWorld}_x(w) \)). Hence, one can expand \( T \) in such a way that all its leaves are labeled by sets containing \( \text{Goal} \), which concludes the proof.

**Lemma 37.** For every database \( D \) over \( \mathcal{S}_{\text{in}}(\Sigma) \), \( (\Sigma_1' \cup \Sigma_2' \cup \Sigma_3', D) \) is chase-terminating.

**Proof.** By Lemma 34, chase sequences can be reordered without changing the number of rule applications such that rules from \( \Sigma_1' \) are applied first, then rules from \( \Sigma_2' \), then rules from \( \Sigma_3' \). Lemma 31 implies that rules from \( \Sigma_1' \) cannot be triggered indefinitely. As the tree structure is finite, if there are infinitely many rule applications performed with a rule from \( \Sigma_2' \), there must be one world null \( w^* \) such that there are infinitely many rules of \( \Sigma_2' \) that are performed mapping \( w \) to \( w^* \). By the construction of Proposition 36, it implies that there exists a database over \( \mathcal{S}_{\text{in}}(\Sigma_2') \) for which \( \Sigma_2' \) does not terminate, which is against our assumptions on \( \Sigma_2' \). Finally, \( \Sigma_3' \) does not contain any existentially quantified variable, hence only finitely many rules can be triggered.

Lemma 18 is a direct consequence of Propositions 35, 36 and Lemma 37.

**C Proofs of Section 6**

**Lemma 23.** The set \( \mathcal{M} \) is not enumerable up to equivalence.

**Proof by Contradiction.**

1. Suppose for a contradiction that the lemma does not hold. Then, there is an enumerator \( P \) that outputs a sequence of TMs that includes \( \mathcal{M} \) up to equivalence. That is, the enumerator \( P \) outputs an infinite sequence \( M_1, M_2, \ldots \) of TMs such that:

   • For each \( i \geq 1 \), we have that \( M_i \in \mathcal{M} \).
   • For each \( M \in \mathcal{M} \), there is some \( i \geq 1 \) such that \( M \) and \( M_i \) are equivalent.

   Two TM \( M \) and \( M' \) are equivalent if, for each word \( w \), we have that \( M \) accepts \( w \) iff \( M' \) accepts \( w \).

2. Consider the sequence \( p_1, p_2, \ldots \) of natural numbers such that \( p_1 = 1 \) and \( p_i \) is the smallest prime with \( p_i > p_{i-1} \) for each \( i \geq 2 \). Note that this sequence is infinite by Euclid’s theorem.

3. By (2): there is an infinite sequence \( D_1, D_2, \ldots \) of databases such that

\[
D_i = \{ \text{ed}(u_1, u_2), \ldots, \text{ed}(u_{p_{i+1}}, u_1) \}
\]

for each \( i \geq 1 \).

4. Consider the TM \( \mathcal{M}_d \) that, on input \( w \), performs the computation:

   (a) Check if \( w \) corresponds to a database \( D \) that only contains facts defined over \( \text{ed} \). If this is not the case, then reject.

   (b) If \( D \) can be homomorphically embedded into a database such as \( \{ \text{ed}(u_1, u_2), \ldots, \text{ed}(u_{k-1}, u_k) \} \) where \( k \) is smaller or equal than the number of nulls in \( D \), then reject.

   (c) If \( \text{ed}(u, u) \in D \) for some null \( u \), then accept.
(d) If there is some $i \geq 1$ such that (i) there are less or the same number of nulls in $D_i$ than in $D$, (ii) $M_i$ accepts some serialisation that corresponds to $D_i$, and (iii) there is a homomorphism $h : D \to D_i$; then reject. Otherwise, accept.

5. By (4): the TM $M_d$ halts on all inputs. Note the following remarks about instruction (4.d):
   - The TM $M_i$ accepts some serialisation that corresponds to $D_i$ if $M_i$ accepts any such serialisation. Therefore, for each instantiation of $i$, the TM $M_d$ only needs to check one (arbitrarily chosen) serialisation of $D_i$ when executing (4.d).
   - When executing (4.d), the TM $M_d$ only needs to check a finite amount of instantiations of $i \geq 1$ before rejecting with confidence due to condition (4.d.i).

6. After this enumeration, we prove that $M_d$ does satisfy (iii) in Definition 5 by contradiction.

7. By (4.a), (5), and (6): the TM $M_d$ is in $M$.

8. By (4): $M_d$ diagonalises over $M_1, M_2, \ldots$ and $D_1, D_2, \ldots$. That is, for any given $i \geq 1$, $M_d$ accepts $D_i$ iff $M_i$ rejects $D_i$.
   - If $M_i$ accepts $D_i$, then $M_d$ rejects $D_i$ in (4.d).
   - If $M_i$ rejects $D_i$, then $M_d$ accepts $D_i$ in (4.d). Note that, if we assume that $M_d$ rejects $D_i$ in this case we obtain a contradiction; namely, we can conclude that $p$ evenly divides $q$ for some prime numbers $p, q > 1$ with $p \neq q$.

9. Contradiction by (1), (7), and (8): the enumerator $P$ is incomplete since it fails to print out a TM that is equivalent to $M_d$, which is in $M$.

Suppose for a contradiction that there are some words $w$ and $v$ that correspond to some databases $D$ and $E$ such that $D$ and $E$ only contain facts defined over $ed$, $M_d$ accepts $D$, $M_d$ rejects $E$, and there is some homomorphism $h : D \to E$. We conduct a case-by-case analysis to show that this assumption results in a contradiction:

- Assume that $D$ is accepted due to instruction (4.c). Then, $ed(u, u) \in D$ for some null $u$ and hence, $ed(t, t) \in E$ for some null $t$ since $h : D \to E$. Therefore, $M_d$ accepts $E$ due to (4.c) ($\Rightarrow$).
- Assume that $D$ is accepted due instruction (4.d). Two possible cases arise:
  - By definition $E$ is a database that only contains facts defined over the predicate $ed$. Hence, $E$ cannot be rejected due to (4.a).
  - If $E$ is rejected due to (4.b), then $E$ can be hom-embedded into a path over $ed$. Therefore, $D$ can also be hom-embedded into the same path since $h : D \to E$ and $M_d$ rejects $D$ due to (4.b) ($\Rightarrow$).
- Assume that $E$ is rejected due to instruction (4.d).

1. There is some $i \geq 1$ and a homomorphism $g$ such that (i) the number of nulls in $i$ is smaller than the number of nulls in $E$, (ii) $g : E \to D_i$, and (iii) the TM $M_i$ accepts the database $D_i$.

2. By (1): $g \circ h : D \to D_i$.

3. If we assume that $p_{i+1}$ is smaller or equal than the number of nulls in $D$, then $M_d$ rejects $D$ due to (4.d) ($\Rightarrow$). Therefore, we conclude that $p_{i+1}$ is strictly greater than the number of nulls in $D$.

4. If we assume that $D$ can be homomorphically embedded into a path over $ed$, then $M_d$ rejects $D$ due to (4.b). Hence, we assume that this is not the case.

5. We obtain a contradiction from (2), (3), and (4).
